Markovianizing Cost of Tripartite Quantum States

Eyuri Wakakuwa, Akihito Soeda and Mio Murao

***Abstract*—We introduce and analyze a task that we call *Markovianization*, in which a tripartite quantum state is transformed to a quantum Markov chain by a randomizing operation on one of the three subsystems. We consider cases where the initial state is the tensor product of n copies of a tripartite state ρ^{ABC}, and is transformed to a quantum Markov chain conditioned by B^n with a small error, using a random unitary operation on A^n. In an asymptotic limit of infinite copies and vanishingly small error, we analyze the *Markovianizing cost*, that is, the minimum cost of randomness per copy required for Markovianization. For tripartite pure states, we derive a single-letter formula for the Markovianizing costs. Counterintuitively, the Markovianizing cost is not a continuous function of states, and can be arbitrarily large even if the state is close to a quantum Markov chain. Our results have an application in analyzing the cost of resources for simulating a bipartite unitary gate by local operations and classical communication.**

I. INTRODUCTION

Tripartite quantum states for which the quantum conditional mutual information (QCMI) is zero are called *short quantum Markov chains*, or *Markov states* for short [1]. They play important roles, e.g., in analyzing the cost of quantum state redistribution [2], [3], investigating effects of the initial system-environment correlation on the dynamics of quantum states [4], and computing the free energy of quantum many-body systems [5].

In analogy to the quantum mutual information (QMI) of a bipartite state quantifying a distance to the closest product states, it would be natural to expect a similar relation between QCMI of a tripartite state and Markov states. However, this conjecture has been falsified [6](see also [7], [8]). The recent results show that the relation between QCMI and Markov states is not so straightforward [6]–[10], particularly when compared to the relation between QMI and product states.

From an operational point of view, QMI quantifies the minimum cost of randomness required for destroying the correlation between two quantum systems in an asymptotic limit of infinite copies [11]. This fact and its variants including single-shot cases are called *decoupling theorems*, and have played a significant role in the development of quantum information theory for a decade [12]–[17]. In a simple analogy, one may ask the following question: Is QCMI equal to the minimum cost of randomness required for transforming a tripartite state to a Markov state?

In this paper, we address this question, and answer in the negative. We derive a single-letter formula for the "Markovianizing cost" of pure states, that is, the minimum cost of randomness per copy required for Markovianizing tripartite pure states in the asymptotic limit of infinite copies. The obtained formula is not equal to QCMI, or not even a continuous function of states. Moreover, the Markovianizing cost of a state can be arbitrarily large, regardless of how close the state is to a Markov state. In the proof, we improve a random coding method using the Haar distributed random unitary ensemble, which is widely used in the proof of the decoupling theorems, by incorporating the mathematical structure of Markov states.

There are two ways for defining the property of tripartite quantum states being "approximately Markov": one by the condition that the state is close to a Markov state, on which our definition of Markovianization in this paper is based; and the other by the condition that the state is *approximately recoverable* [10], i.e., there exists a quantum operation $\mathcal{E} : B \to BC$ such that $\rho^{ABC} \approx \mathcal{E}(\rho^{AB})$. Ref. [10] proved that the latter condition has a direct connection with QCMI, namely, small QCMI implies recoverability with a small error.

In [18], we introduce another formulation of the Markovianizing cost by employing the concept of recoverability, and prove that the cost function is equal to the one obtained in this paper for pure states. We then apply the results in analyzing the cost of entanglement and classical communication for simulating a bipartite unitary gate by local operations and classical communication [19]. As a consequence, we prove in [20] that there is a trade-off relation between the entanglement cost and the number of rounds of communication for a two-party distributed quantum information processing.

The structure of this paper is as follows. In Section II, we review mathematical theorems regarding the structure of quantum Markov chains, which are extensively used in this paper. In Section III, we introduce the formal definition of Markovianization, and describe the main results. Outlines of proofs of the main results are presented in Section IV. In Section V, we describe properties of the Markovianizing cost. In Section VI, we calculate the Markovianizing cost of particular classes of tripartite pure states to illustrate its properties. Conclusions are given in Section VII. See Appendices for detailed proofs.

Notations. A Hilbert space associated with a quantum system A is denoted by $\mathcal{H}^A$, and its dimension is denoted by d_A. For $\rho \in \mathcal{S}(\mathcal{H}^A)$, we denote $\mathrm{supp}[\rho] \subseteq \mathcal{H}^A$ by $\mathcal{H}^A_\rho$. A system composed of two subsystems A and B is denoted by

AB. When M and N are linear operators on $\mathcal{H}^A$ and $\mathcal{H}^B$, respectively, we denote $M \otimes N$ as $M^A \otimes N^B$ for clarity. We abbreviate $|\psi\rangle^A \otimes |\phi\rangle^B$ as $|\psi\rangle^A |\phi\rangle^B$. The identity operator on a Hilbert space is denoted by I. We denote $(M^A \otimes I^B)|\psi\rangle^{AB}$ as $M^A|\psi\rangle^{AB}$, and $(M^A \otimes I^B)\rho^{AB}(M^A \otimes I^B)^\dagger$ as $M^A\rho^{AB}M^{A\dagger}$. We abbreviate $M^{AB}(\rho^A \otimes I^B)M^{\dagger AB}$ as $M^{AB}\rho^A M^{\dagger AB}$. When $\mathcal{E}$ is a quantum operation on A, we denote $(\mathcal{E} \otimes \mathrm{id}^B)(\rho^{AB})$ as $(\mathcal{E}^A \otimes \mathrm{id}^B)(\rho^{AB})$ or $\mathcal{E}^A(\rho^{AB})$. For ρ^{AB}, ρ^A represents $\mathrm{Tr}_B[\rho^{AB}]$. We denote $|\psi\rangle\langle\psi|$ simply as ψ. A system composed of n identical systems of A is denoted by A^n or $\bar{A}$, and the corresponding Hilbert space is denoted by $(\mathcal{H}^A)^{\otimes n}$ or $\mathcal{H}^{\bar{A}}$. The Shannon entropy of a probability distribution is denoted as $H(\{p_j\}_j)$, and the von Neumann entropy of a state ρ^A is interchangeably denoted by $S(\rho^A)$ and $S(A)_\rho$. $\log x$ represents the base 2 logarithm of x.

II. PRELIMINARIES

In this section, we present a decomposition of a Hilbert space called the *Koashi-Imoto (KI) decomposition*, which is introduced in [21] and is extensively used in the following part of this paper. We then summarize a result in [1], which states that the structure of Markov states is characterized by the KI decomposition.

A. Koashi-Imoto Decomposition

For any set of states on a quantum system, operations on that system are classified into two categories: one that do not change any state in the set, and the other that changes at least one state in the set. It is proved in [21] that there exists an effectively unique way of decomposing a Hilbert space into a direct-sum form, in such a way that all quantum operations that do not change a given set of states have a simple form with respect to the decomposition. We call this decomposition of the Hilbert space as the *Koashi-Imoto decomposition*, or the *KI decomposition* for short. As we verify in Remark in this section, the KI decomposition is equivalently be represented in the form of a tensor product of three Hilbert spaces. Theorem 3 in [21], which proves the existence of the KI decomposition, is described in this tensor-product form as follows.

Theorem 1 ([21], see also Theorem 9 in [1]) Consider a quantum system A described by a finite dimensional Hilbert space $\mathcal{H}^A$. Associated to any set of states $\mathfrak{S} := \{\rho_k\}_k$ on A, there exist three Hilbert spaces $\mathcal{H}^{a_0}$, $\mathcal{H}^{a_L}$, $\mathcal{H}^{a_R}$, an orthonormal basis $\{|j\rangle\}_{j\in J}$ of $\mathcal{H}^{a_0}$ and a linear isometry Γ from $\mathcal{H}^A_{\mathfrak{S}} := \mathrm{supp}(\sum_k \rho_k) \subseteq \mathcal{H}^A$ to $\mathcal{H}^{a_0} \otimes \mathcal{H}^{a_L} \otimes \mathcal{H}^{a_R}$, such that the following three properties hold. (For later convenience, we exchange labels L and R in the original formulation.)

1) The states in $\mathfrak{S}$ are decomposed by Γ as

$$\Gamma\rho_k\Gamma^\dagger = \sum_{j\in J} p_{j|k} |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes \rho_{j|k}^{a_R} \tag{1}$$

with some probability distribution $\{p_{j|k}\}_{j\in J}$ on $J := \{1, \cdots, \mathrm{dim}\mathcal{H}^{a_0}\}$, states $\omega_j \in \mathcal{S}(\mathcal{H}^{a_L})$ and $\rho_{j|k} \in \mathcal{S}(\mathcal{H}^{a_R})$.

2) A quantum operation $\mathcal{E}$ on $\mathcal{S}(\mathcal{H}^A_{\mathfrak{S}})$ leaves all ρ_k invariant if and only if there exists an isometry $U : \mathcal{H}^A_{\mathfrak{S}} \to \mathcal{H}^A_{\mathfrak{S}} \otimes \mathcal{H}^E$ such that a Stinespring dilation of $\mathcal{E}$ is given by $\mathcal{E}(\tau) = \mathrm{Tr}_E[U\tau U^\dagger]$, and that U is decomposed by Γ as

$$(\Gamma \otimes I^E)U\Gamma^\dagger = \sum_{j\in J} |j\rangle\langle j|^{a_0} \otimes U_j^{a_L} \otimes I_j^{a_R}. \tag{2}$$

Here, I_j are the identity operators on $\mathcal{H}_j^{a_R} := \mathrm{supp}\sum_k \rho_{j|k}$, and $U_j : \mathcal{H}_j^{a_L} \to \mathcal{H}_j^{a_L} \otimes \mathcal{H}^E$ are isometries that satisfy $\mathrm{Tr}_E[U_j\omega_j U_j^\dagger] = \omega_j$ for all j, where $\mathcal{H}_j^{a_L} := \mathrm{supp}\,\omega_j$.

3) Γ satisfies

$$\mathrm{img}\Gamma = \bigoplus_{j\in J} \mathcal{H}_j^{a_0} \otimes \mathcal{H}_j^{a_L} \otimes \mathcal{H}_j^{a_R}, \tag{3}$$

where $\mathcal{H}_j^{a_0}$ are one-dimensional subspaces of $\mathcal{H}^{a_0}$ spanned by $|j\rangle$.

4) $\mathcal{H}^{a_0}$, $\mathcal{H}^{a_L}$ and $\mathcal{H}^{a_R}$ are minimal in the sense that

$$\dim \mathcal{H}^{a_L} = \max_{j\in J} \dim \mathcal{H}_j^{a_L},\ \dim \mathcal{H}^{a_R} = \max_{j\in J} \dim \mathcal{H}_j^{a_R}$$

and

$$\forall j \in J,\ \exists k \text{ s.t. } p_{j|k} > 0.$$

We call Γ as the *KI isometry on system A with respect to* $\mathfrak{S}$. The KI decomposition and the corresponding KI isometry are uniquely determined from $\mathfrak{S}$, up to trivial changes of the basis (Lemma 7 in [21]). The dimensions of $\mathcal{H}^{a_0}$, $\mathcal{H}^{a_L}$ and $\mathcal{H}^{a_R}$ are at most d_A. An algorithm for obtaining the KI decomposition is proposed in [21].

It is also proved in [21] that the sets of states $\{\rho_{j|k}\}_k$ in (1) are *irreducible* in the following sense.

Lemma 2 (Corollary of Lemma 6 in [21]) The set of states $\{\rho_{j|k}\}_k$ in (1) satisfies the following properties.

1) If a linear operator N on $\mathcal{H}_j^{a_R} := \mathrm{supp}\sum_k \rho_{j|k}$ satisfies $p_{j|k}N\rho_{j|k} = p_{j|k}\rho_{j|k}N$ for all k, then $N = cI_j^{a_R}$ for a complex number c, where $I_j^{a_R}$ is the identity operator on $\mathcal{H}_j^{a_R}$.
2) If a linear operator $N : \mathcal{H}_j^{a_R} \to \mathcal{H}_{j'}^{a_R}$ $(j \neq j')$ satisfies $p_{j|k}N\rho_{j|k} = p_{j'|k}\rho_{j'|k}N$ for all k, then $N = 0$.

Let us now describe an extension of the KI decomposition to a bipartite quantum states, which is introduced in [1]. Associated to any bipartite state $\Psi^{AA'} \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^{A'})$, there exists a set of states on A to which system A can be *steered* through $\Psi^{AA'}$, i.e., the set of states that can be prepared by performing a measurement on A' on the state $\Psi^{AA'}$ and post-selecting one outcome. The KI decomposition of A with respect to the set is then associated to $\Psi^{AA'}$. It happens that any quantum operation on A which leaves all states in the set invariant also leaves $\Psi^{AA'}$ invariant, and vice versa. Hence the set of operations preserving $\Psi^{AA'}$ is completely characterized by the corresponding KI decomposition. More precisely, we have the following statements.

Definition 3 Consider quantum systems A and A' described by finite dimensional Hilbert spaces $\mathcal{H}^A$ and $\mathcal{H}^{A'}$, respectively.

The KI decomposition of system A with respect to a bipartite state $\Psi^{AA'} \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^{A'})$ is defined as the KI decomposition of A with respect to the following set $\mathfrak{S}_{\Psi^{A'\to A}}$ of states, i.e., using $\mathcal{L}(\mathcal{H}^{A'})$ to denote the set of linear operators on $\mathcal{H}^{A'}$,

$$\mathfrak{S}_{\Psi^{A'\to A}} := \{\rho \in \mathcal{S}(\mathcal{H}^A) \mid \exists M \in \mathcal{L}(\mathcal{H}^{A'}) \text{ s.t. } \rho = \mathrm{Tr}_{A'}[M^{A'}\Psi^{AA'}M^{\dagger A'}]\}. \quad (4)$$

The KI isometry on system A with respect to $\Psi^{AA'}$ is defined as that with respect to $\mathfrak{S}_{\Psi^{A'\to A}}$.

Lemma 4 (See the proof of Theorem 6 in [1] and Equality (14) therein.) Let Γ be the KI isometry on A with respect to $\Psi^{AA'}$, and define $\mathcal{H}_\Psi^A := \mathrm{supp}[\Psi^A] \subseteq \mathcal{H}^A$. Γ satisfies the following properties.

1) Γ gives

$$\Psi_{KI}^{AA'} := \Gamma^A \Psi^{AA'} \Gamma^{\dagger A} = \sum_{j\in J} p_j |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes \varphi_j^{a_R A'} \quad (5)$$

with some probability distribution $\{p_j\}_{j\in J}$, orthonormal basis $\{|j\rangle\}_{j\in J}$ of $\mathcal{H}^{a_0}$, states $\omega_j \in \mathcal{S}(\mathcal{H}^{a_L})$ and $\varphi_j \in \mathcal{S}(\mathcal{H}^{a_R} \otimes \mathcal{H}^{A'})$.

2) A quantum operation $\mathcal{E}$ on $\mathcal{S}(\mathcal{H}_\Psi^A)$ leaves $\Psi^{AA'}$ invariant only if there exists an isometry $U : \mathcal{H}_\Psi^A \to \mathcal{H}_\Psi^A \otimes \mathcal{H}^E$ such that a Stinespring dilation of $\mathcal{E}$ is given by $\mathcal{E}(\tau) = \mathrm{Tr}_E[U\tau U^\dagger]$, and that U is decomposed by Γ as (2), in which case we define $\mathcal{H}_j^{a_R} := \mathrm{supp}\varphi_j^{a_R}$.

We call (5) as the *KI decomposition of* $\Psi^{AA'}$ *on* A. The following lemma, regarding the equivalence between the KI isometries of two bipartite states, immediately follows.

Lemma 5 The following conditions are equivalent when $\mathcal{H}_{\Psi_1}^A = \mathcal{H}_{\Psi_2}^A = \mathcal{H}^A$:

1) A quantum operation on A leaves a state $\Psi_1^{AA'}$ invariant if and only if it leaves a state $\Psi_2^{AA''}$ invariant.
2) The KI isometries on A with respect to $\Psi_1^{AA'}$ and $\Psi_2^{AA''}$ are the same.

We define the sub-KI isometries as follows.

Definition 6 Consider a bipartite state $\Psi^{AA'}$, three Hilbert spaces $\mathcal{H}^{a_0}$, $\mathcal{H}^{a_L}$, $\mathcal{H}^{a_R}$ and let Γ be a linear isometry from $\mathcal{H}_\Psi^A$ to $\mathcal{H}^{a_0} \otimes \mathcal{H}^{a_L} \otimes \mathcal{H}^{a_R}$. We call Γ as a sub-KI isometry on system A with respect to $\Psi^{AA'}$ if it satisfies Condition 1) in Lemma 4.

B. Markov States

A tripartite quantum state Υ^{ABC} is called a Markov state conditioned by B if it satisfies $I(A:C|B)_\Upsilon = 0$. It is proved in [1] that the structure of Markov states is characterized by the KI decomposition as follows.

Theorem 7 (See Theorem 6 in [1] and the proof thereof.) The following three conditions are equivalent:

1) Υ^{ABC} is a Markov state conditioned by B.
2) There exist three Hilbert spaces $\mathcal{H}^{b_0}$, $\mathcal{H}^{b_L}$, $\mathcal{H}^{b_R}$ and a linear isometry Γ from $\mathcal{H}_\Upsilon^B := \mathrm{supp}[\Upsilon^B]$ to $\mathcal{H}^{b_0} \otimes \mathcal{H}^{b_L} \otimes \mathcal{H}^{b_R}$ such that Υ^{ABC} is decomposed by Γ as

$$\Gamma^B \Upsilon^{ABC} \Gamma^{\dagger B} = \sum_i q_i |i\rangle\langle i|^{b_0} \otimes \sigma_i^{Ab_L} \otimes \phi_i^{b_R C} \quad (6)$$

with some probability distribution $\{q_i\}_i$, orthonormal basis $\{|i\rangle\}_i$ of $\mathcal{H}^{b_0}$, states $\sigma_i \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^{b_L})$ and $\phi_i \in \mathcal{S}(\mathcal{H}^{b_R} \otimes \mathcal{H}^C)$.
3) Υ^{ABC} is decomposed in the form of (6) with Γ being the KI isometry on B with respect to Υ^{BC}.
4) There exist quantum operations $\mathcal{R}$ from B to BC and $\mathcal{R}'$ from B to AB such that

$$\Upsilon^{ABC} = \mathcal{R}(\Upsilon^{AB}) = \mathcal{R}'(\Upsilon^{BC}). \quad (7)$$

We call (6) as a *Markov decomposition* of a Markov state Υ^{ABC} (Figure 1).

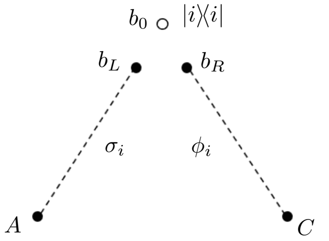

Fig. 1. A graphical representation of the Markov decomposition of the Markov state (6). Each vertex corresponds to a quantum system, and the white circle represents a 'classical' system, where the state of the whole system is diagonal with respect to $|i\rangle^{b_0}$. The dotted lines represent mixed states. The whole state is the probabilistic mixture of the above state with probability q_i, namely, $\sum_i q_i |i\rangle\langle i|^{b_0} \otimes \sigma_i^{Ab_L} \otimes \phi_i^{b_R C}$.

Remark: The KI decomposition is first proved in [21] by an algorithmic construction, and by an algebraic proof in [1] afterward. A similar decomposition is derived in [22] and [23] in the context of "information preserving structure". In these literatures, the decomposition is given in the form of the direct sum of Hilbert spaces as $\bigoplus_j \mathcal{H}_j^L \otimes \mathcal{H}_j^R$. This is equivalent to the decomposition in the form of a tensor product of three Hilbert spaces described in this section, as verified by choosing $\mathcal{H}^{a_0}$, $\mathcal{H}^{a_L}$ and $\mathcal{H}^{a_R}$ such that $\dim \mathcal{H}^{a_0} = |J|$, $\dim \mathcal{H}^{a_L} = \max_{j\in J} \mathcal{H}_j^L$ and $\dim \mathcal{H}^{a_R} = \max_{j\in J} \mathcal{H}_j^R$. The corresponding KI isometry is defined as

$$\Gamma := \sum_{j\in J} |j\rangle^{a_0} \otimes (\Gamma_{L,j} \otimes \Gamma_{R,j}) P_j \quad (8)$$

where $\Gamma_{L,j} : \mathcal{H}_j^L \to \mathcal{H}^{a_L}$ and $\Gamma_{R,j} : \mathcal{H}_j^R \to \mathcal{H}^{a_R}$ are linear isometries and P_j is the projection onto $\mathcal{H}_j^L \otimes \mathcal{H}_j^R \in \mathcal{H}$. As stressed in [21], $\mathcal{H}^{a_0}$ in (1) holds the "classical" part of information possessed by ρ_k, $\mathcal{H}^{a_R}$ the "quantum" part, and $\mathcal{H}^{a_L}$ the redundant part.

III. DEFINITIONS AND MAIN RESULTS

In this section, we introduce the formal definition of Markovianization, and state the main results on the Markovianizing cost of tripartite pure states. The outlines of proofs are given in Section IV. Rigorous proofs will be given in Appendix B and C.

Definition 8 A tripartite state ρ^{ABC} is *Markovianized* with the randomness cost R on A, conditioned by B, if the following statement holds. That is, for any $\epsilon > 0$, there exists n_ϵ such that for any $n \geq n_\epsilon$, we find a random unitary operation $\mathcal{V}_n : \tau \mapsto 2^{-nR} \sum_{k=1}^{2^{nR}} V_k \tau V_k^\dagger$ on A^n and a Markov state $\Upsilon^{A^n B^n C^n}$ conditioned by B^n that satisfy

$$\left\| \mathcal{V}_n^{A^n}(\rho^{\otimes n}) - \Upsilon^{A^n B^n C^n} \right\|_1 \leq \epsilon. \tag{9}$$

The *Markovianizing cost* of ρ^{ABC} is defined as $M_{A|B}(\rho^{ABC}) := \inf\{R \mid \rho^{ABC}$ is Markovianized with the randomness cost R on A, conditioned by $B\}$.

The following theorem is the main contribution of this work. The outline of the proof is given in the next section.

Theorem 9 Let $|\Psi\rangle^{ABC}$ be a pure state, and let

$$\Psi_{KI}^{AC} = \sum_{j\in J} p_j |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes \varphi_j^{a_R C} \tag{10}$$

be the KI decomposition of Ψ^{AC} on A. Then we have

$$M_{A|B}(\Psi^{ABC}) = H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R}).$$

Based on this theorem, it is possible to compute the Markovianizing cost of pure states once we obtain the KI decomposition of its bipartite reduced density matrix. However, the algorithm for obtaining the KI decomposition, which is proposed in [21], involves repeated application of decompositions of the Hilbert space into subspaces, and is difficult to execute in general.

Below we propose an algorithm by which we can compute the Markovianizing cost for a particular class of pure states, without obtaining an explicit form of the KI decomposition. The algorithm is based on the following theorem, which connects the Markovianizing cost of a pure state and the Petz recovery map corresponding to the state. Here, the *Petz recovery map* of a tripartite state Ψ^{ABC} from A to AC, an idea first introduced in [1], is defined by

$$\mathcal{R}_\Psi^{A\to AC}(\tau) = (\Psi^{AC})^{\frac{1}{2}} (\Psi^A)^{-\frac{1}{2}} \tau (\Psi^A)^{-\frac{1}{2}} (\Psi^{AC})^{\frac{1}{2}} \qquad (\forall \tau \in \mathcal{S}(\mathcal{H}^A)).$$

A proof of the theorem will be given in Appendix C.

Theorem 10 Let $|\Psi\rangle^{ABC}$ be a pure state, such that a CPTP map $\mathcal{E}$ on $\mathcal{S}(\mathcal{H}_\Psi^A)$ defined by

$$\mathcal{E} := \mathrm{Tr}_C \circ \mathcal{R}_\Psi^{A\to AC} \tag{11}$$

is self-adjoint. Define another CPTP map $\mathcal{E}_\infty$ by

$$\mathcal{E}_\infty := \lim_{N\to\infty} \frac{1}{N} \sum_{n=1}^{N} \mathcal{E}^n, \tag{12}$$

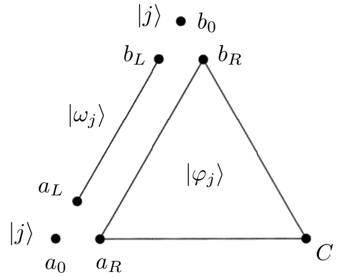

Fig. 2. A graphical representation of the KI decomposition of tripartite pure states (15). Each vertex corresponds to a quantum system. The solid lines express pure states. The whole state is the superposition of the above states with the probability amplitude $\sqrt{p_j}$, namely, $\sum_{j\in J} \sqrt{p_j} |j\rangle^{a_0} |j\rangle^{b_0} |\omega_j\rangle^{a_L b_L} |\varphi_j\rangle^{a_R b_R C}$.

and consider the state

$$\Psi_\infty^{ABC} := \mathcal{E}_\infty^A(|\Psi\rangle\langle\Psi|^{ABC}). \tag{13}$$

Then we have

$$M_{A|B}(\Psi^{ABC}) = S(\Psi_\infty^{ABC}). \tag{14}$$

Due to this theorem, the Markovianizing cost of pure states can be computed by the following algorithm, based on a matrix representation of CPTP maps. Here, $\{|k\rangle\}_{k=1}^{d_A}$ is an orthonormal basis of $\mathcal{H}^A$, and $[\cdot]_{kl,mn}$ denotes a matrix element in the kl-th row and the mn-th column. (See also Remark in Appendix C-B.)

1) Compute d_A^2-dimensional square matrices Λ_1, Λ_2 and Λ given by

$$\begin{aligned}[\Lambda_1]_{kl,mn} &= \langle k|(\Psi^A)^{\frac{1}{2}}|m\rangle\langle n|(\Psi^A)^{\frac{1}{2}}|l\rangle, \\ [\Lambda_2]_{kl,mn} &= \mathrm{Tr}\left[\langle k|^A(\Psi^{AC})^{\frac{1}{2}}|m\rangle^A\langle n|^A(\Psi^{AC})^{\frac{1}{2}}|l\rangle^A\right]\end{aligned}$$

   and $\Lambda = \Lambda_2\Lambda_1^{-1}$, where the superscript -1 denotes the generalized inverse.
2) Check the hermiticity of Λ, which is equivalent to the self-adjointness of $\mathcal{E}$. If it is Hermitian, continue to Step 3. If not, this algorithm is not applicable.
3) Compute a matrix Λ_∞ corresponding to $\mathcal{E}_\infty$, which is given by the projection onto the eigensubspace of Λ corresponding to the eigenvalue 1. Then compute $\tilde{\Lambda}_\infty = \Lambda_\infty\Lambda_1$.
4) Compute $\Omega_\infty^{AA'}$ given by

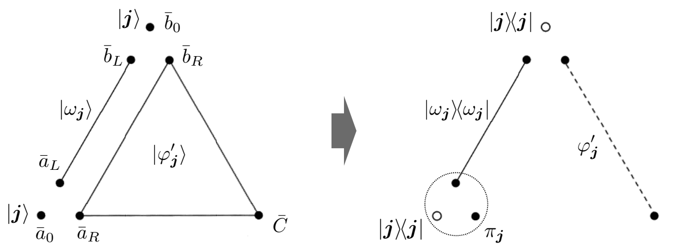
$$\Omega_\infty^{AA'} = \sum_{klmn} [\tilde{\Lambda}_\infty]_{kl,mn} |k\rangle\langle l|^A \otimes |m\rangle\langle n|^{A'}.$$

5) Compute the Shannon entropy of the eigenvalues of $\Omega_\infty^{AA'}$, which is equal to $M_{A|B}(\Psi^{ABC})$.

IV. OUTLINE OF PROOFS OF THE MAIN THEOREMS

In this section, we describe the outline, main concepts and technical ingredients for the proofs of Theorem 9 and 10. Detailed proofs are given in Appendix B and C.

We first introduce an adaptation of the KI decomposition to *tripartite* pure states as follows.



$|\boldsymbol{j}\rangle$
$\bar{b}_0$
$\bar{b}_L$
$\bar{b}_R$
$|\omega_{\boldsymbol{j}}\rangle$
$|\varphi'_{\boldsymbol{j}}\rangle$
$\bar{a}_L$
$|\boldsymbol{j}\rangle$
$\bar{a}_0$
$\bar{a}_R$
$\bar{C}$
$|\boldsymbol{j}\rangle\langle\boldsymbol{j}|$
$|\omega_{\boldsymbol{j}}\rangle\langle\omega_{\boldsymbol{j}}|$
$\varphi'_{\boldsymbol{j}}$
$|\boldsymbol{j}\rangle\langle\boldsymbol{j}|$
$\pi_{\boldsymbol{j}}$

Fig. 3. A graphical representation of the state transformation from $\Psi'_{n,\delta}$ in (17) to $\bar{\Psi}_{n,\delta}$ in (19) by a random unitary operation given by (18)

Lemma 11 Let $|\Psi\rangle^{ABC}$ be a tripartite pure state and suppose that the KI decomposition of Ψ^{AC} on A is given by

$$\Gamma^A\Psi^{AC}\Gamma^{\dagger A} = \sum_{j\in J} p_j |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes \varphi_j^{a_R C}.$$

There exists a linear isometry $\Gamma' : \mathcal{H}_\Psi^B \to \mathcal{H}^{b_0} \otimes \mathcal{H}^{b_L} \otimes \mathcal{H}^{b_R}$ that decomposes $|\Psi\rangle^{ABC}$ together with Γ as

$$(\Gamma^A \otimes \Gamma'^B)|\Psi\rangle^{ABC} = \sum_{j\in J} \sqrt{p_j}|j\rangle^{a_0}|j\rangle^{b_0}|\omega_j\rangle^{a_L b_L}|\varphi_j\rangle^{a_R b_R C}, \tag{15}$$

where $|\omega_j\rangle^{a_L b_L}$ and $|\varphi_j\rangle^{a_R b_R C}$ are purifications of $\omega_j^{a_L}$ and $\varphi_j^{a_R C}$, respectively, and $\langle j|j'\rangle^{b_0} = \delta_{jj'}$. Moreover, Γ' is the sub-KI isometry on B with respect to Ψ^{BC}.

Proof: The existence of Γ' follows from Uhlmann's theorem ([24], see Appendix A-A). It is straightforward to verify that Γ' is the sub-KI isometry, since we have

$$\Gamma'^B\Psi^{BC}\Gamma'^{\dagger B} = \sum_{j\in J} p_j |j\rangle\langle j|^{b_0} \otimes \omega_j^{b_L} \otimes \varphi_j^{b_R C}$$

from (15). ■

We call (15) as the *KI decomposition of* $|\Psi\rangle^{ABC}$ *on A and B* (Figure 2), and denote it by $|\Psi_{KI}\rangle$.

A. For Theorem 9: Achievability

The direct part of Theorem 9 is formulated by the following inequality:

$$M_{A|B}(\Psi^{ABC}) \leq H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R}). \tag{16}$$

The outline of the proof is as follows. The state $|\Psi^{ABC}\rangle^{\otimes n}$ is local unitarily equivalent to $|\Psi_{KI}\rangle^{\otimes n}$, which is almost equal to the state defined by

$$|\Psi'_{n,\delta}\rangle := \sum_{\boldsymbol{j}\in J_{n,\delta}} \sqrt{p_{\boldsymbol{j}}}|\boldsymbol{j}\rangle^{\bar{a}_0}|\boldsymbol{j}\rangle^{\bar{b}_0}|\omega_{\boldsymbol{j}}\rangle^{\bar{a}_L\bar{b}_L}\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}|\varphi_{\boldsymbol{j}}\rangle^{\bar{a}_R\bar{b}_R\bar{C}} \tag{17}$$

for sufficiently large n. Here, we have introduced notations $\boldsymbol{j} = j_1\cdots j_n$, $\varphi_{\boldsymbol{j}} = \varphi_{j_1}\otimes\cdots\otimes\varphi_{j_n}$ and $\omega_{\boldsymbol{j}} = \omega_{j_1}\otimes\cdots\otimes\omega_{j_n}$. $J_{n,\delta}$ is the δ-strongly typical set with respect to the probability distribution $\{p_j\}_j$, and $\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}$ is the projection onto the conditionally typical subspace of $\varphi_{\boldsymbol{j}}^{\bar{a}_R}$ conditioned by $\boldsymbol{j}$. Consider a unitary operation on $\mathrm{supp}\,[\Psi_{n,\delta}'^{\bar{a}_0\bar{a}_L\bar{a}_R}]$ of the form

$$V := \sum_{\boldsymbol{j}\in J_{n,\delta}} |\boldsymbol{j}\rangle\langle\boldsymbol{j}|^{\bar{a}_0} \otimes I_{\boldsymbol{j}}^{\bar{a}_L} \otimes v_{\boldsymbol{j}}^{\bar{a}_R}, \tag{18}$$

where $I_{\boldsymbol{j}}^{\bar{a}_L}$ is the identity operator on $\mathrm{supp}\,\omega_{\boldsymbol{j}}^{\bar{a}_L}$ and $v_{\boldsymbol{j}}^{\bar{a}_R}$ is a unitary on the support of $\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}$. We apply $V^{\bar{a}_0\bar{a}_L\bar{a}_R}$ on $\Psi'_{n,\delta}$ by independently choosing $v_{\boldsymbol{j}}^{\bar{a}_R}$ from the Haar distributed random unitary ensemble for each $\boldsymbol{j}$. By this random unitary operation, the state (17) is transformed to the following state

$$\bar{\Psi}_{n,\delta} := \sum_{\boldsymbol{j}\in J_{n,\delta}} p_{\boldsymbol{j}}|\boldsymbol{j}\boldsymbol{j}\rangle\langle\boldsymbol{j}\boldsymbol{j}|^{\bar{a}_0\bar{b}_0} \otimes |\omega_{\boldsymbol{j}}\rangle\langle\omega_{\boldsymbol{j}}|^{\bar{a}_L\bar{b}_L} \otimes \pi_{\boldsymbol{j}}^{\bar{a}_R} \otimes \varphi_{\boldsymbol{j}}'^{\bar{b}_R\bar{C}}, \tag{19}$$

where $\varphi'_{\boldsymbol{j}} := \mathrm{Tr}_{a_R}[\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}|\varphi_{\boldsymbol{j}}\rangle\langle\varphi_{\boldsymbol{j}}|]$ and $\pi_{\boldsymbol{j}}^{\bar{a}_R} = \Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}/\mathrm{Tr}[\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R}]$. $\bar{\Psi}_{n,\delta}$ is a Markov state conditioned by B (Figure 3).

To Markovianize $|\Psi^{ABC}\rangle^{\otimes n}$, it is sufficient that we approximate the transformation from (17) to (19) by $\mathcal{V}_n$ with a vanishingly small error, where V_k in $\mathcal{V}_n$ are unitaries which are decomposed by $\Gamma^{\otimes n}$ as (18). By a random coding method and the operator Chernoff bound [11], it is shown that a sufficient number of unitaries in $\mathcal{V}_n$ for this approximation is almost equal to the inverse of the minimum nonzero eigenvalue of (19), and is given as $H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R})$ per copy. We note that the error ϵ converges exponentially with n to zero.

B. For Theorem 9: Optimality

The converse part of Theorem 9 is formulated by the following inequality:

$$M_{A|B}(\Psi^{ABC}) \geq H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R}). \tag{20}$$

Let us first assume tentatively that a Markov decomposition of $\Upsilon^{\bar{A}\bar{B}\bar{C}}$ in (9) is given by

$$(\Gamma'^B)^{\otimes n}\Upsilon^{\bar{A}\bar{B}\bar{C}}(\Gamma'^B)^{\otimes n} = \sum_{\boldsymbol{j}\in J^n} p'_{\boldsymbol{j}}|\boldsymbol{j}\rangle\langle\boldsymbol{j}|^{b_0} \otimes \sigma_{\boldsymbol{j}}^{\bar{A}b_L} \otimes \phi_{\boldsymbol{j}}^{b_R\bar{C}}, \tag{21}$$

with Γ' being the KI isometry on B with respect to Ψ^{BC}. In this case, it is not difficult to show that the amount of randomness per copy required for transforming $|\Psi^{\otimes n}\rangle^{\bar{A}\bar{B}\bar{C}}$ to $\Upsilon^{\bar{A}\bar{B}\bar{C}}$ is bounded below by the R.H.S. of (20). Indeed, in order to transform $|\Psi_{KI}\rangle^{\otimes n}$ to a Markov state in the form of (21), it is necessary that (i) the off-diagonal terms with respect to $|\boldsymbol{j}\rangle$ vanish, and (ii) the correlation between $\bar{a}_R$ and $\bar{b}_R\bar{C}$ in the state $|\varphi_{\boldsymbol{j}}\rangle^{\bar{a}_R\bar{b}_R\bar{C}}$ is destroyed for each $\boldsymbol{j}$. An optimal way for satisfying these two conditions is transforming the state (17) close to a state of the form (19). Since the entropy of the state (19) is approximately equal to $n(H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R}))$, the cost of randomness required for this transformation is at least about $H(\{p_j\}_{j\in J}) + 2\sum_{j\in J} p_j S(\varphi_j^{a_R})$ bits per copy.

However, it might be possible in general that the amount of randomness can be further reduced by appropriately choosing

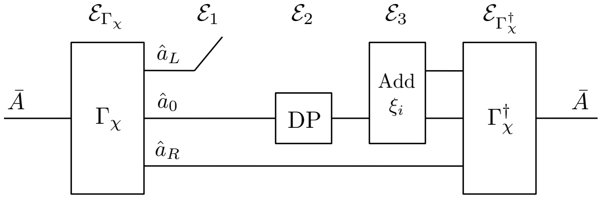


Fig. 4. A graphical representation of the channel $\mathcal{E}_\chi$. Due to the completely dephasing channel denoted as DP, the system $\hat{a}_0$ has some capacity to transmit classical information, but has no capacity to transfer entanglement. The system $\hat{a}_R$ has some capacity to transfer entanglement.

$\Upsilon^{\bar{A}\bar{B}\bar{C}}$ and the corresponding KI decomposition of $\bar{B}$. We shall see that our choice presented above is indeed optimal. At the core of the proof lies the following lemma.

Lemma 12 Let Ψ^{AC} be a bipartite quantum state, and let $\Gamma_\Psi : \mathcal{H}_\Psi^A \to \mathcal{H}^{a_0} \otimes \mathcal{H}^{a_L} \otimes \mathcal{H}^{a_R}$ be the KI isometry on A with respect to Ψ^{AC}. For any n and $\epsilon > 0$, let $\chi^{\bar{A}\bar{C}}$ be a state that satisfies

$$\left\| (\Psi^{\otimes n})^{\bar{A}\bar{C}} - \chi^{\bar{A}\bar{C}} \right\|_1 \leq \epsilon, \tag{22}$$

and let $\Gamma_\chi : \mathcal{H}_\chi^{\bar{A}} \to \mathcal{H}^{\hat{a}_0} \otimes \mathcal{H}^{\hat{a}_L} \otimes \mathcal{H}^{\hat{a}_R}$ be a sub-KI isometry on $\bar{A}$ with respect to $\chi^{\bar{A}\bar{C}}$. Denoting the decompositions $\Gamma_\Psi^A \Psi^{AC} \Gamma_\Psi^{\dagger A}$ and $\Gamma_\chi^{\bar{A}} \chi^{\bar{A}\bar{C}} \Gamma_\chi^{\dagger \bar{A}}$ by Ψ_{KI}^{AC} and $\chi_{sKI}^{\bar{A}\bar{C}}$, respectively, we have

$$\begin{aligned} &\frac{1}{n} \left(S(\hat{a}_0)_{\chi_{sKI}} + 2S(\hat{a}_R|\hat{a}_0)_{\chi_{sKI}} \right) \\ &\qquad \geq S(a_0)_{\Psi_{KI}} + 2S(a_R|a_0)_{\Psi_{KI}} - \zeta'_\Psi(\epsilon) \log d_A. \end{aligned} \tag{23}$$

Here, $\zeta'_\Psi(\epsilon)$ is a function of $\epsilon > 0$ and Ψ, which does not depend on n, and satisfies $\lim_{\epsilon \to 0} \zeta'_\Psi(\epsilon) = 0$. See Equality (90) in Appendix B-D for a rigorous definition.

Proof Outline for Lemma 12: Assume here for simplicity that

$$(\mathcal{H}_\Psi^A)^{\otimes n} = \mathcal{H}_\chi^{\bar{A}} = \mathcal{H}^{\bar{A}}, \tag{24}$$

and suppose the decompositions of Ψ^{AC} and that of $\chi^{\bar{A}\bar{C}}$ are given by

$$\Psi_{KI}^{AC} = \sum_{j \in J} p_j |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes \varphi_j^{a_R C}$$

and

$$\chi_{sKI}^{\bar{A}\bar{C}} = \sum_i q_i |i\rangle\langle i|^{\hat{a}_0} \otimes \xi_i^{\hat{a}_L} \otimes \phi_i^{\hat{a}_R \bar{C}}, \tag{25}$$

respectively. Consider a quantum channel $\mathcal{E}_\chi$ on $\bar{A}$ defined by

$$\mathcal{E}_\chi(\tau) = \Gamma_\chi^\dagger \left(\sum_i |i\rangle\langle i|^{\hat{a}_0} \mathrm{Tr}_{\hat{a}_L} [\Gamma_\chi \tau \Gamma_\chi^\dagger] |i\rangle\langle i|^{\hat{a}_0} \otimes \xi_i^{\hat{a}_L} \right) \Gamma_\chi, \tag{26}$$

which is decomposed as $\mathcal{E}_{\Gamma_\chi^\dagger} \circ \mathcal{E}_3 \circ \mathcal{E}_2 \circ \mathcal{E}_1 \circ \mathcal{E}_{\Gamma_\chi}$. The maps $\mathcal{E}_{\Gamma_\chi}$ and $\mathcal{E}_{\Gamma_\chi^\dagger}$ are isometry channels corresponding to Γ_χ and $\Gamma_\chi^\dagger$, respectively; $\mathcal{E}_1$ is discarding of system $\hat{a}_L$; $\mathcal{E}_2$ is the completely dephasing channel on $\hat{a}_0$ with respect to the basis $|i\rangle$; $\mathcal{E}_3$ is appending of the state $\xi_i^{\hat{a}_L}$, conditioned by $\hat{a}_0$ (Figure 4). The linearity and the complete positivity of $\mathcal{E}_\chi$ immediately follows from (26), and the trace-preserving property results from the fact that Γ_χ satisfies Condition (3).

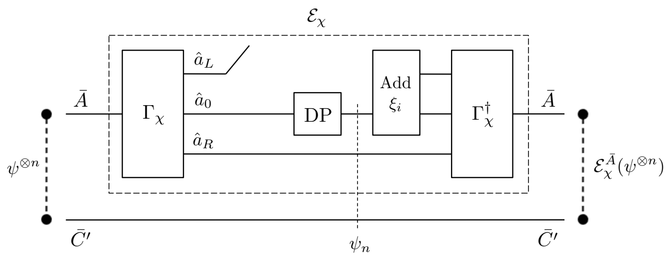

Fig. 5. A graphical representation of the state transformation of $\psi^{\otimes n}$ under $\mathcal{E}_\chi$. The channel $\mathcal{E}_\chi$ has little effect on the state $\psi^{\otimes n}$ on average. In particular, it almost conserves the correlation that $\psi^{\otimes n}$ initially has. Thus the intermediate state ψ_n has the same amount of correlation due to the monotonicity.

The state $\chi^{\bar{A}\bar{C}}$ is invariant under the action of $\mathcal{E}_\chi$, and thus $(\Psi^{\otimes n})^{\bar{A}\bar{C}}$ is almost unchanged due to (22). By extending the data compression theorem for quantum mixed-state ensembles [25], it follows that any state of the form $(\psi^{\otimes n})^{\bar{A}\bar{C}'}$ is almost unchanged by $\mathcal{E}_\chi$ on average, as long as $\psi^A = \Psi^A$ holds and the KI isometry on A with respect to $\psi^{AC'}$ is equal to Γ_Ψ. We consider $\psi^{AC'}$ such that its KI decomposition on A is, up to an additional decomposition on C', given by

$$\psi_{KI}^{AC'} = \sum_{j \in J} p_j |j\rangle\langle j|^{a_0} \otimes \omega_j^{a_L} \otimes |\tilde{\varphi}_j\rangle\langle\tilde{\varphi}_j|^{a_R c'_R} \otimes |j\rangle\langle j|^{c'_0},$$

where $|\tilde{\varphi}_j\rangle^{a_R c'_R}$ is a purification of $\varphi_j^{a_R}$. The correlation between $\bar{A}$ and $\bar{C}'$ in the state $\psi^{\otimes n}$, measured by QMI, is equal to

$$\begin{aligned} nI(A : C')_\psi &= nI(a_0 a_L a_R : c'_0 c'_R)_{\psi_{KI}} \\ &= n \left(S(a_0)_{\psi_{KI}} + 2S(a_R|a_0)_{\psi_{KI}} \right). \end{aligned} \tag{27}$$

It can be shown that this amount of correlation is almost conserved under $\mathcal{E}_\chi$.

Due to the monotonicity of QMI, it follows that the correlation between $\hat{a}_0\hat{a}_L\hat{a}_R$ and $\bar{C}'$ is approximately equal to (27) at any intermediate step of $\mathcal{E}_\chi$ (see Figure 4). After the action of the completely dephasing channel $\mathcal{E}_2$, the system $\hat{a}_0$ holds no quantum correlation with other systems, and thus the correlation between $\hat{a}_0\hat{a}_R$ and $\bar{C}'$ is bound to be at most $S(\hat{a}_0) + 2S(\hat{a}_R|\hat{a}_0)$ (Figure 5). Moreover, the state on $\hat{a}_0\hat{a}_R$ after $\mathcal{E}_2$ is almost equal to $\chi_{sKI}^{\hat{a}_0\hat{a}_R}$ due to (22). A more detailed argument reveals that

$$\begin{aligned} &S(\hat{a}_0)_{\chi_{sKI}} + 2S(\hat{a}_R|\hat{a}_0)_{\chi_{sKI}} \\ &\qquad \gtrsim n \left(S(a_0)_{\psi_{KI}} + 2S(a_R|a_0)_{\psi_{KI}} \right), \end{aligned}$$

and consequently proving (23).

C. For Theorem 10

Let us first express (11), (12) and (13) in terms of the "decomposed" Hilbert space $\mathcal{H}^{a_0} \otimes \mathcal{H}^{a_L} \otimes \mathcal{H}^{a_R}$. A Kraus representation of a map $\mathcal{E}$ defined by (11) is given by $\mathcal{E}(\cdot) = \sum_{kl} E_{kl} (\cdot) E_{kl}^\dagger$, with the Kraus operators

$$E_{kl} := \langle k|^C (\Psi^{AC})^{\frac{1}{2}} |l\rangle^C (\Psi^A)^{-\frac{1}{2}}. \tag{28}$$

Let Γ be the KI isometry on A with respect to Ψ^{AC}, and suppose the KI decomposition of Ψ^{AC} is given by (10). For each E_{kl}, we have

$$\hat{E}_{kl} := \Gamma E_{kl} \Gamma^{\dagger} = \sum_{j \in J} |j\rangle\langle j|^{a_0} \otimes I_j^{a_L} \otimes e_{j,kl}^{a_R}, \tag{29}$$

where

$$e_{j,kl} := \langle k|^{C} (\varphi_j^{a_R C})^{\frac{1}{2}} |l\rangle^{C} (\varphi_j^{a_R})^{-\frac{1}{2}}. \tag{30}$$

By an extension of Lemma 2, it follows that $\{e_{j,kl}\}_{kl}$ is irreducible in the sense that it satisfies Property 1) and 2). It is straightforward to verify from (30) that maps $\mathcal{E}_j^{a_R}$ on $\mathcal{S}(\mathcal{H}_j^{a_R})$, defined by $\mathcal{E}_j^{a_R}(\cdot) := \sum_{k,l} e_{j,kl}(\cdot)e_{j,kl}^{\dagger}$ $(j = 1, \cdots, |J|)$, are trace-preserving. Representations of $\mathcal{E}$ and $\mathcal{E}_{\infty}$ in the decomposed Hilbert space are given by

$$\hat{\mathcal{E}}(\cdot) = \sum_{kl} \hat{E}_{kl}(\cdot)\hat{E}_{kl}^{\dagger} \tag{31}$$

and $\hat{\mathcal{E}}_{\infty} := \lim_{n\to\infty}(1/N)\sum_{n=1}^{N} \hat{\mathcal{E}}^n$, respectively, and that of Ψ_{∞}^{ABC} is given by $\hat{\mathcal{E}}_{\infty}(|\Psi_{KI}\rangle\langle\Psi_{KI}|)$.

Due to $\mathcal{E} \circ \mathcal{E}_{\infty} = \mathcal{E}_{\infty}$ and the irreducibility of $\{e_{j,kl}\}_{kl}$, we have

$$\hat{\mathcal{E}}_{\infty}(|\Psi_{KI}\rangle\langle\Psi_{KI}|) = \sum_{j\in J} p'_j |j\rangle\langle j|^{a_0} \otimes \tilde{\omega}_j \otimes \pi_j^{a_R}, \tag{32}$$

where $\{p'_j\}_{j\in J}$ is a probability distribution and $\tilde{\omega}_j$ $(j \in J)$ are states on $a_L b_0 b_L b_R C$. Explicit forms of $\tilde{\omega}_j$ and p'_j are obtained as follows. First, from (29), (31) and the trace-preserving property of $\mathcal{E}_j$, we have

$$\begin{aligned} \mathrm{Tr}[\langle j|^{a_0}\hat{\mathcal{E}}(\hat{\tau})|j\rangle^{a_0}] &= \mathrm{Tr}[(\mathrm{id}^{a_L} \otimes \mathcal{E}_j^{a_R})(\langle j|^{a_0}\hat{\tau}|j\rangle^{a_0})] \\ &= \mathrm{Tr}[\langle j|^{a_0}\hat{\tau}|j\rangle^{a_0}] \end{aligned}$$

for any j and $\hat{\tau} = \Gamma\tau\Gamma^{\dagger}$ $(\tau \in \mathcal{S}(\mathcal{H}_{\Psi}^{A}))$. This implies that the probability amplitude with respect to the basis $\{|j\rangle\}_j$ is conserved by $\hat{\mathcal{E}}$, as well as by $\hat{\mathcal{E}}_{\infty}$. Thus we have $p'_j = p_j$. Observe from (29) that $\hat{\mathcal{E}}$ and $\hat{\mathcal{E}}_{\infty}$ do not affect the system a_L, which implies

$$\tilde{\omega}_j = |\omega_j\rangle\langle\omega_j|^{a_L b_L} \otimes |j\rangle\langle j|^{b_0} \otimes \varphi_j^{b_R C}.$$

Hence the von Neumann entropy of Ψ_{∞}^{ABC}, which is equal to that of (32), is given by

$$S(\Psi_{\infty}^{ABC}) = H(\{p_j\}_j) + \sum_j p_j \left(S(\varphi_j^{b_R C}) + S(\pi_j^{a_R}) \right).$$

In addition, that the self-adjointness of $\mathcal{E}$ implies $\varphi_j^{a_R} = \pi_j^{a_R}$. Since $|\varphi_j\rangle^{a_R b_R C}$ is a purification of $\varphi_j^{b_R C}$, we finally obtain that

$$S(\Psi_{\infty}^{ABC}) = H(\{p_j\}_j) + 2\sum_j p_j S(\varphi_j^{a_R}) = M_{A|B}(\Psi^{ABC}).$$

V. PROPERTIES

In this section, we describe properties of the Markovianizing cost of tripartite quantum states. We first consider arbitrary (possibly mixed) states, and then focus on the case of pure states.

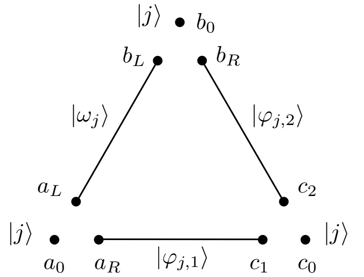

Fig. 6. A graphical representation of a decomposition of tripartite pure states for which the Markovianizing cost is equal to QCMI. The whole state is the superposition of the above states with the probability amplitude $\sqrt{p_j}$, namely, $\sum_{j\in J}\sqrt{p_j}|j\rangle^{a_0}|j\rangle^{b_0}|j\rangle^{c_0}|\omega_j\rangle^{a_L b_L}|\varphi_{j,1}\rangle^{a_R c_1}|\varphi_{j,2}\rangle^{b_R c_2}$.

A. General Properties

Let ρ^{ABC} be an arbitrary tripartite state on finite dimensional quantum systems A, B and C. The Markovianizing cost of ρ^{ABC} satisfies

$$I(A:C|B)_{\rho} \leq M_{A|B}(\rho^{ABC}) \leq I(A:BC)_{\rho}. \tag{33}$$

The second inequality directly follows from the fact that decoupling A from BC is sufficient for converting the state to a Markov state and that the cost of randomness for decoupling bipartite states is asymptotically given by QMI [11]. The first inequality is proved in Appendix D. Consequently, the Markovianizing cost is equal to zero only for Markov states.

The Markovianizing cost satisfies a kind of the data processing inequality, namely, that

$$M_{A|B}(\mathcal{E}^C(\rho^{ABC})) \leq M_{A|B}(\rho^{ABC})$$

under any quantum operation $\mathcal{E}$ on C. This is because any random unitary operation $\mathcal{V}_n$ on A^n satisfying (9) also satisfies

$$\left\| \mathcal{V}_n^{A^n}([\mathcal{E}^C(\rho)]^{\otimes n}) - (\mathcal{E}^C)^{\otimes n}(\Upsilon^{A^n B^n C^n}) \right\|_1 \leq \epsilon,$$

and $(\mathcal{E}^C)^{\otimes n}(\Upsilon^{A^n B^n C^n})$ is a Markov state conditioned by B^n. As a consequence, an upper bound on the Markovianizing cost of a mixed state is obtained as

$$M_{A|B}(\rho^{ABC}) \leq M_{A|B}(\psi_{\rho}^{ABC'}),$$

where $|\psi_{\rho}\rangle^{ABC'}$ is a purification of ρ^{AB}. This is because there always exists a quantum operation $\mathcal{F}_{\rho} : C' \to C$ such that $\mathcal{F}_{\rho}(\psi_{\rho}^{ABC'}) = \rho^{ABC}$.

B. Pure States

Let us now consider pure states, based on the result presented in Section III. First, we see that the Markovianizing cost $M_{A|B}$ of two pure states Ψ_1 and Ψ_2 are equal if there exist λ $(0 < \lambda \leq 1)$ and $\sigma^C \in \mathcal{S}(\mathcal{H}^C)$ such that

$$\Psi_2^{AC} = \lambda\Psi_1^{AC} + (1-\lambda)\Psi_1^{A} \otimes \sigma^C. \tag{34}$$

This is because $\Psi_1^A = \Psi_2^A$ and the KI decompositions of A with respect to Ψ_1^{AC} and Ψ_2^{AC} are equal, the latter of which follows from Lemma 5. Indeed, any quantum operation on A

which keeps Ψ_1^{AC} invariant also keeps Ψ_2^{AC} invariant and vice versa, as can be seen by observing from (34) that we have

$$\Psi_1^{AC} = \frac{1}{\lambda}\Psi_2^{AC} - \frac{1-\lambda}{\lambda}\Psi_2^{A} \otimes \sigma^{C}.$$

Second, we obtain a necessary and sufficient condition for the Markovianizing cost of pure states to be equal to QCMI as follows (Figure 6).

Theorem 13 Let $|\Psi\rangle^{ABC}$ be a pure state, and let

$$|\Psi_{KI}\rangle^{ABC} = \sum_{j\in J}\sqrt{p_j}|j\rangle^{a_0}|j\rangle^{b_0}|\omega_j\rangle^{a_L b_L}|\varphi_j\rangle^{a_R b_R C},$$

be its KI decomposition on A and B (see Lemma 11). Then we have $M_{A|B}(\Psi^{ABC}) = I(A:C|B)_\Psi$ if and only if there exists an isometry $\Gamma'' : \mathcal{H}^C \to \mathcal{H}^{c_0}\otimes\mathcal{H}^{c_1}\otimes\mathcal{H}^{c_2}$ such that φ_j is decomposed as

$$\Gamma''^{C}|\varphi_j\rangle^{a_R b_R C} = |j\rangle^{c_0}|\varphi_{j,1}\rangle^{a_R c_1}|\varphi_{j,2}\rangle^{b_R c_2},$$

where $\langle j|j'\rangle = \delta_{j,j'}$.

Proof: We have

$$\begin{aligned}
& I(A:C|B)_\Psi = I(A:C)_\Psi = I(a_0 a_L a_R : C)_{\Psi_{KI}} \\
= \ & I(a_0 : C)_{\Psi_{KI}} + I(a_L a_R : C|a_0)_{\Psi_{KI}} \\
= \ & I(a_0 : C)_{\Psi_{KI}} + \sum_j p_j I(a_R : C)_{\varphi_j},
\end{aligned}$$

as well as

$$M_{A|B}(\Psi^{ABC}) = H(a_0) + 2\sum_j p_j S(a_R)_{\varphi_j}.$$

Since $\Psi_{KI}^{a_0 C}$ is a classical-quantum state, we have $I(a_0 : C)_{\Psi_{KI}} \leq H(a_0)$ with equality if and only if $\{\mathrm{supp}[\varphi_j^C]\}_j$ is mutually orthogonal. We also have $2S(a_R)_{\varphi_j} \geq I(a_R : C)_{\varphi_j}$, which is saturated if and only if $2S(a_R)_{\varphi_j} - I(a_R : C)_{\varphi_j} = I(a_R : b_R)_{\varphi_j} = 0$ (see Inequality (45) in Appendix A-B). Hence we have $M_{A|B}(\Psi^{ABC}) = I(A:C|B)_\Psi$ if and only if

$$\Psi_{KI}^{AB} = \sum_{j\in J} p_j |j,j\rangle\langle j,j|^{a_0 b_0} \otimes |\omega_j\rangle\langle\omega_j|^{a_L b_L} \otimes \varphi_j^{a_R} \otimes \varphi_j^{b_R},$$

which concludes the proof due to Uhlmann's theorem ([24], see Appendix A-A). ■

An example of states that satisfy the above conditions is given in Section VI-C.

VI. EXAMPLES

In this section, we consider examples of pure states to illustrate discontinuity and asymmetry of the Markovianizing cost. We also give an example of states for which the Markovianizing cost is equal to QCMI.

A. Discontinuity

We consider tripartite pure states that are expressed as

$$\begin{aligned}
|\Psi_\lambda\rangle \ = \ & \sqrt{\frac{d^2\lambda - 1}{d^2-1}}|00\rangle^B|\Phi_d\rangle^{AC} \\
& + \sqrt{\frac{1-\lambda}{d^2-1}}\sum_{k,l=1}^{d}|kl\rangle^B|k\rangle^A|l\rangle^C,
\end{aligned}$$

where $d = \mathrm{dim}\mathcal{H}^A = \mathrm{dim}\mathcal{H}^C$, $\mathrm{dim}\mathcal{H}^B = d^2+1$, $1/d^2 \leq \lambda \leq 1$, and Φ_d is a maximally entangled state of Schmidt rank d, defined as

$$|\Phi_d\rangle = \frac{1}{\sqrt{d}}\sum_{k=1}^{d}|k\rangle|k\rangle. \tag{35}$$

For this state, we have

$$I(A:C|B)_{\Psi_\lambda} \ = \ 2\log d - h(\lambda) - (1-\lambda)\log(d^2-1), \tag{36}$$

where h denotes the binary entropy defined by $h(\lambda) = -\lambda\log\lambda - (1-\lambda)\log(1-\lambda)$. The state is a Markov state if and only if $\lambda = 1/d^2$. The distance to the closest Markov state is bounded from above by

$$\begin{aligned}
\left\|\Psi_\lambda^{ABC} - \Psi_{1/d^2}^{ABC}\right\|_1 \ &= \ 2\sqrt{1 - |\langle\Psi_\lambda|\Psi_{1/d^2}\rangle|^2} \\
&= \ 2\sqrt{\frac{d^2\lambda-1}{d^2-1}}.
\end{aligned} \tag{37}$$

The reduced state on AC is given by

$$\begin{aligned}
\Psi_\lambda^{AC} \ &= \ \frac{d^2\lambda-1}{d^2-1}|\Phi_d\rangle\langle\Phi_d|^{AC} + \frac{1-\lambda}{d^2-1}I^A\otimes I^C \\
&= \ \lambda'|\Phi_d\rangle\langle\Phi_d|^{AC} + (1-\lambda')\,\pi^A\otimes\pi^C,
\end{aligned}$$

where π is the d-dimensional maximally mixed state and $\lambda' = (d^2\lambda-1)/(d^2-1)$. Hence the Markovianizing cost does not depend on λ' when $\lambda' > 0$, as we proved in Section V-B. As directly verified by considering the case of $\lambda' = 1$, the Markovianizing cost is equal to $2\log d$ for $\lambda' > 0$. Taking the symmetry of Ψ_λ between A and C into account, we obtain

$$M_{A|B}(\Psi_\lambda) = M_{C|B}(\Psi_\lambda) = \begin{cases} 2\log d & (\lambda > 1/d^2) \\ 0 & (\lambda = 1/d^2) \end{cases}. \tag{38}$$

Hence the Markovianizing cost is not a continuous function of states. In a particular case where $\lambda = 2/d^2$, the Markovianizing cost grows logarithmically with respect to the dimension of the system, whereas QCMI, as well as the distance to the closest Markov state, approaches zero as indicated by (36) and (37).

We note that Ψ_λ^{ABC} is "approximately recoverable" if λ is close to $1/d^2$, i.e., it satisfies Equalities (7) approximately if $\lambda \approx 1/d^2$. Indeed, since Ψ_{1/d^2} is a Markov state, there exist quantum operations $\mathcal{R} : B \to BC$ and $\mathcal{R}' : B \to AB$ such that

$$\Psi_{1/d^2}^{ABC} = \mathcal{R}(\Psi_{1/d^2}^{AB}) = \mathcal{R}'(\Psi_{1/d^2}^{BC}).$$

Due to the triangle inequality and the monotonicity of the trace distance (see Appendix A-A), we have

$$\begin{aligned}&\left\|\Psi_\lambda^{ABC}-\mathcal{R}(\Psi_\lambda^{AB})\right\|_1\\ \le\ &\left\|\Psi_\lambda^{ABC}-\Psi_{1/d^2}^{ABC}\right\|_1+\left\|\Psi_{1/d^2}^{ABC}-\mathcal{R}(\Psi_{1/d^2}^{AB})\right\|_1\\ &+\left\|\mathcal{R}(\Psi_{1/d^2}^{AB})-\mathcal{R}(\Psi_\lambda^{AB})\right\|_1\\ \le\ &2\left\|\Psi_\lambda^{ABC}-\Psi_{1/d^2}^{ABC}\right\|_1\end{aligned}$$

as well as

$$\left\|\Psi_\lambda^{ABC}-\mathcal{R}'(\Psi_\lambda^{BC})\right\|_1\le 2\left\|\Psi_\lambda^{ABC}-\Psi_{1/d^2}^{ABC}\right\|_1.$$

Thus Equality (37) implies

$$\left\|\Psi_\lambda^{ABC}-\mathcal{R}(\Psi_\lambda^{AB})\right\|_1,\ \left\|\Psi_\lambda^{ABC}-\mathcal{R}'(\Psi_\lambda^{BC})\right\|_1\le 4\sqrt{\frac{d^2\lambda-1}{d^2-1}}.$$

B. Asymmetry

We consider tripartite pure states that are expressed as

$$|\Psi_\lambda\rangle=\sqrt{\lambda}|0\rangle^B|\Phi_d\rangle^{AC}+\sqrt{1-\lambda}|0\rangle^A|\Phi_d\rangle^{BC},$$

where $d=\dim\mathcal{H}^C$, $\dim\mathcal{H}^A=\dim\mathcal{H}^B=d+1$, $0\le\lambda\le 1$ and Φ_d is a maximally entangled state defined by (35). The reduced state on AC is given by

$$\Psi_\lambda^{AC}=\lambda|\Phi_d\rangle\langle\Phi_d|^{AC}+(1-\lambda)\,|0\rangle\langle 0|^A\otimes\pi^C. \tag{39}$$

Note that $|\Psi_d\rangle^{AC}$ does not have any $|0\rangle^A|0\rangle^C$ component. Hence the CPTP maps on A defined as (11) and (12) are given by

$$\begin{aligned}\mathcal{E}(\tau)\ =\ &\mathrm{Tr}[P_1\tau]\cdot\pi_1+\mathrm{Tr}[P_0\tau]\cdot|0\rangle\langle 0|\\ &+\frac{1}{d}P_1\tau P_0+\frac{1}{d}P_0\tau P_1\end{aligned}$$

and

$$\mathcal{E}_\infty(\tau)=\mathrm{Tr}[P_1\tau]\cdot\pi_1+\mathrm{Tr}[P_0\tau]\cdot|0\rangle\langle 0|,$$

respectively, where $P_0=|0\rangle\langle 0|$, $P_1=I-P_0$ and $\pi_1=P_1/d$. It is straightforward to verify that $\mathcal{E}$ is self-adjoint. By applying $\mathcal{E}_\infty$ to $|\Psi_\lambda\rangle$ on A, we obtain that

$$\begin{aligned}\Psi_\infty^{ABC}\ =\ &\lambda\,\pi_1^A\otimes|0\rangle\langle 0|^B\otimes\pi_1^C\\ &+(1-\lambda)\,|0\rangle\langle 0|^A\otimes|\Phi_d\rangle\langle\Phi_d|^{BC}.\end{aligned}$$

Therefore, due to Theorem 10, the Markovianizing cost is given by

$$M_{A|B}(\Psi_\lambda)=h(\lambda)+2\lambda\log d.$$

On the other hand, from (39), the Markovianizing costs $M_{C|B}$ of Ψ_λ does not depend on λ when $\lambda>0$ as proved in Section V-B. Thus we have

$$M_{C|B}(\Psi_\lambda)=\begin{cases}2\log d & (\lambda>0)\\ 0 & (\lambda=0)\end{cases}$$

in the same way as (38). Hence the Markovianizing cost is not symmetric in A and C, as opposed to QCMI, which satisfies $I(A:C|B)=I(C:A|B)$.

C. States for which the Markovianizing cost coincides QCMI

We consider states that are expressed as

$$|\Psi_{\{\lambda_k\}}\rangle:=\sum_{k=1}^d\sqrt{\lambda_k}|k\rangle^A|k\rangle^B|k\rangle^C,$$

where $\lambda_k\ge 0$ and $\sum_{k=1}^d\lambda_k=1$. These states satisfy conditions in Theorem 13, thus the Markovianizing cost is given by

$$M_{A|B}(\Psi_{\{\lambda_k\}})=I(A:C|B)_{\Psi_{\{\lambda_k\}}}=H(\{\lambda_k\}_k).$$

VII. CONCLUSIONS AND DISCUSSIONS

We have introduced the task of Markovianization, and derived a single-letter formula for the minimum cost of randomness required for Markovianizing tripartite pure states. We have also proposed an algorithm to compute the Markovianizing cost of a class of pure states without obtaining an explicit form of the Koashi-Imoto decomposition. We then have computed the Markovianizing cost for certain pure states, and revealed its discontinuity and asymmetry. Our results have an application in analyzing optimal costs of resources for simulating a bipartite unitary gate by local operations and classical communication [19]. Some open questions are generalization to mixed states, formulation of a classical analog of Markovianization, in addition to finding an alternative formulation of Markovianization for which we obtain QCMI as the cost function.

In [18], we have introduced and analyzed an alternative formulation of Markivianization and the Markovianizing cost. Instead of requiring Condition (9), we require that the state after a random unitary operation is "approximately recoverable", i.e., it satisfies Equalities (7) approximately. For pure states, we have proved that the Markovianizing cost in that case is equal to the one obtained in this paper.

ACKNOWLEDGMENT

The authors thank Tomohiro Ogawa and Masato Koashi for useful discussions.

APPENDIX A
MATHEMATICAL PRELIMINARIES

In this appendix, we summarize frequently used facts and technical tools used when studying quantum Shannon theory and also in the following appendices. Readers who are familiar with the material may skip this section. For the references, see e.g. [26]–[28].

A. Trace Distance and Uhlmann’s Theorem

The trace distance between two quantum states $\rho, \sigma \in \mathcal{S}(\mathcal{H})$ is defined by

$$d(\rho,\sigma) := \frac{1}{2}\|\rho-\sigma\|_1 = \frac{1}{2}\mathrm{Tr}\left[\sqrt{(\rho-\sigma)^2}\right].$$

In the following, we omit the coefficient $1/2$ for simplicity. For pure states $|\psi\rangle, |\phi\rangle \in \mathcal{H}$, the trace distance takes a simple form of

$$\| |\psi\rangle\!\langle\psi| - |\phi\rangle\!\langle\phi| \|_1 = 2\sqrt{1-|\langle\psi|\phi\rangle|^2}.$$

For $\rho, \sigma, \tau \in \mathcal{S}(\mathcal{H})$, we have

$$\|\rho-\tau\|_1 \le \|\rho-\sigma\|_1 + \|\sigma-\tau\|_1 ,$$

which is called the *triangle inequality*. The trace distance is monotonically nonincreasing under quantum operations, i.e., it satisfies

$$\|\rho-\sigma\|_1 \ge \|\mathcal{E}(\rho)-\mathcal{E}(\sigma)\|_1$$

for any linear CPTP map $\mathcal{E} : \mathcal{S}(\mathcal{H}) \to \mathcal{S}(\mathcal{H}')$. As a particular case, the trace distance between two states on a composite system is nonincreasing under taking the partial trace, that is, for $\rho, \sigma \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B)$ we have

$$\|\rho^{AB}-\sigma^{AB}\|_1 \ge \|\rho^A-\sigma^A\|_1.$$

Consider two states $\rho, \sigma \in \mathcal{S}(\mathcal{H}^A)$ satisfying $\|\rho-\sigma\|_1 \le \epsilon$, and let $|\psi_\rho\rangle^{AB}$ and $|\phi_\sigma\rangle^{AB'}$ be purifications of the two states, respectively. If $d_B \le d_{B'}$, there exists an embedding of $\mathcal{H}^B$ into $\mathcal{H}^{B'}$, represented by an isometry from $\mathcal{H}^B$ to $\mathcal{H}^{B'}$, such that

$$\left\| |\psi_\rho\rangle\!\langle\psi_\rho|^{AB'} - |\psi_\sigma\rangle\!\langle\psi_\sigma|^{AB'} \right\|_1 \le 2\sqrt{\epsilon}.$$

This relation is referred to as *Uhlmann’s theorem* ([24], see also Lemma 2.2 in [29]). In the case of $\epsilon = 0$, the above statement implies that all purifications are equivalent up to a local isometry.

The *gentle measurement lemma* (Lemma 9.4.1 in [28]) states that for any $\rho \in \mathcal{S}(\mathcal{H})$, $X \in \mathcal{L}(\mathcal{H})$ and $\epsilon \ge 0$ such that $0 \le X \le I$ and $\mathrm{Tr}[\rho X] \ge 1-\epsilon$, we have

$$\left\| \rho - \frac{\sqrt{X}\rho\sqrt{X}}{\mathrm{Tr}[\rho X]} \right\|_1 \le 2\sqrt{\epsilon}. \qquad (40)$$

As a corollary, when two bipartite states $\rho \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B)$ and $\sigma \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^{B'})$ satisfies $\|\rho^A - \sigma^A\|_1 \le \epsilon$, and Π_σ is the projection onto $\mathrm{supp}[\sigma^A] \subseteq \mathcal{H}^A$, we have

$$\left\| \rho^{AB} - \frac{\Pi_\sigma^A \rho^{AB} \Pi_\sigma^A}{\mathrm{Tr}[\rho^A \Pi_\sigma^A]} \right\|_1 \le 2\sqrt{\epsilon}. \qquad (41)$$

This is because we have

$$\begin{aligned} \epsilon &\ge \left\| \Pi_\sigma \rho^A \Pi_\sigma + \Pi_\sigma^\perp \rho^A \Pi_\sigma^\perp - \sigma^A \right\|_1 \\ &= \left\| \sigma^A - \Pi_\sigma \rho^A \Pi_\sigma \right\|_1 + \mathrm{Tr}[\rho^A \Pi_\sigma^\perp], \end{aligned}$$

where $\Pi_\sigma^\perp$ denotes the projection onto the orthogonal complement of $\mathrm{supp}[\sigma^A] \subseteq \mathcal{H}^A$, and thus have

$$\mathrm{Tr}[\rho^{AB}\Pi_\sigma^A] = \mathrm{Tr}[\rho^A \Pi_\sigma^A] = 1 - \mathrm{Tr}[\rho^A \Pi_\sigma^\perp] \ge 1-\epsilon.$$

B. Quantum Entropies and Mutual Informations

The Shannon entropy of a probability distribution $\{p_x\}_{x\in\mathcal{X}}$ is defined as

$$H(\{p_x\}_{x\in\mathcal{X}}) := -\sum_{x\in\mathcal{X}} p_x \log p_x.$$

The von Neumann entropy of a quantum state $\rho^A \in \mathcal{S}(\mathcal{H}^A)$ is defined as

$$S(\rho^A) = S(A)_\rho := -\mathrm{Tr}[\rho^A \log \rho^A].$$

If ρ^A is a probabilistic mixture of pure states as $\rho^A = \sum_j p_j |\phi_j\rangle\langle\phi_j|$, we have $S(\rho^A) \leq H(\{p_j\}_j)$ with equality if and only if $\{|\phi_j\rangle\}_j$ is mutually orthogonal. The von Neumann entropy is monotonically nondecreasing under random unitary operations, that is, we have $S(A)_\rho \leq S(A)_{\mathcal{V}(\rho)}$ for any random unitary operation $\mathcal{V}$ on A. For a bipartite pure state $|\psi\rangle^{AA'}$, we have

$$S(\psi^A) = S(\psi^{A'}). \tag{42}$$

For a bipartite state $\rho \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B)$, the quantum conditional entropy and the quantum mutual information (QMI) are defined as

$$S(A|B)_\rho = S(AB)_\rho - S(B)_\rho,$$
$$I(A:B)_\rho = S(A)_\rho + S(B)_\rho - S(AB)_\rho,$$

respectively. The von Neumann entropy satisfies the *subadditivity*, expressed as

$$S(A)_\rho + S(B)_\rho \geq S(AB)_\rho, \tag{43}$$

which guarantees the nonnegativity of QMI. The equality holds if and only if $\rho^{AB} = \rho^A \otimes \rho^B$. Applying (43) to $|\psi_\sigma\rangle^{ABC}$, which is a purification of σ^{AC}, and by using (42), we obtain

$$S(C)_\sigma - S(A)_\sigma \leq S(AC)_\sigma. \tag{44}$$

Hence QMI is bounded above as

$$I(A:C)_\rho \leq \min\{2S(A)_\rho, 2S(C)_\rho\}. \tag{45}$$

For any $\rho \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B)$ and quantum operation $\mathcal{E}$ on B, we have

$$S(A|B)_\rho \leq S(A|B)_{\mathcal{E}(\rho)}, \;\; I(A:B)_\rho \geq I(A:B)_{\mathcal{E}(\rho)}. \tag{46}$$

Inequalities (46) are called the *data processing inequality*.

For a tripartite state $\rho \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B \otimes \mathcal{H}^C)$, the quantum conditional mutual information (QCMI) is defined as

$$I(A:C|B)_\rho = S(AB)_\rho + S(BC)_\rho - S(B)_\rho - S(ABC)_\rho.$$

QCMI is nonnegative because of the *strong subadditivity* of the von Neumann entropy [30], which is also equivalent to the data processing inequality. QMI and QCMI are related by a simple relation as

$$I(A:BC)_\rho = I(A:B)_\rho + I(A:C|B)_\rho,$$

which is called the *chain rule*.

For a class of states called the *classical-quantum states*, the quantum conditional entropy and QCMI take simple forms. That is, for states $\rho \in \mathcal{S}(\mathcal{H}^X \otimes \mathcal{H}^A)$ and $\sigma \in \mathcal{S}(\mathcal{H}^X \otimes \mathcal{H}^A \otimes \mathcal{H}^B)$, given as

$$\rho^{XA} = \sum_i p_i |i\rangle\langle i|^X \otimes \rho_i^A,$$
$$\sigma^{XAB} = \sum_i q_i |i\rangle\langle i|^X \otimes \sigma_i^{AB},$$

where $\{|i\rangle\}_i$ is an orthonormal basis of $\mathcal{H}^X$, we have

$$S(A|X)_\rho = \sum_i p_i S(\rho_i^A),$$
$$I(A:B|X)_\sigma = \sum_i q_i I(A:B)_{\sigma_i}.$$

QMI of a classical-quantum state takes the form of

$$I(X:A)_\rho = S(\bar{\rho}^A) - \sum_i p_i S(\rho_i^A),$$

where $\bar{\rho}^A = \sum_i p_i \rho_i^A$. This quantity is equal to the *Holevo information* [31], and satisfies

$$I(X:A)_\rho \leq S(X)_\rho = H(\{p_i\}_i)$$

with equality if and only if $\{\mathrm{supp}[\rho_i^A]\}_i$ is mutually orthogonal.

C. Continuity of Quantum Entropies

Define

$$\eta_0(x) := \begin{cases} -x\log x & (x \leq 1/e) \\ \frac{1}{e} & (x \geq 1/e) \end{cases},$$

$\eta(x) = x + \eta_0(x)$ and $h(x) := \eta_0(x) + \eta_0(1-x)$, where e is the base of the natural logarithm. For two states ρ and σ in a d-dimensional quantum system ($d < \infty$) such that $\|\rho - \sigma\|_1 \leq \epsilon$, we have

$$|S(\rho) - S(\sigma)| \leq \epsilon \log d + \eta_0(\epsilon) \leq \eta(\epsilon)\log d, \tag{47}$$

which is called the *Fannes inequality* [32]. It follows that for two bipartite states $\rho, \sigma \in \mathcal{S}(\mathcal{H}^A \otimes \mathcal{H}^B)$ such that $\|\rho - \sigma\|_1 \leq \epsilon$, we have

$$|S(A|B)_\rho - S(A|B)_\sigma| \leq \eta(\epsilon)\log(d_A d_B^2) \tag{48}$$

and

$$|I(A:B)_\rho - I(A:B)_\sigma| \leq 2\eta(\epsilon)\log(d_A d_B). \tag{49}$$

D. Typical Sequences and Subspaces ([33], [34], see also Appendices in [14] for further details.)

Let X be a discrete random variable with finite alphabet $\mathcal{X}$ and probability distribution $p_x = \Pr\{X = x\}$ where $x \in \mathcal{X}$. A sequence $\boldsymbol{x} = (x_1, \cdots, x_n) \in \mathcal{X}^n$ is said to be *δ-weakly typical with respect to* $\{p_x\}_{x\in\mathcal{X}}$ if it satisfies

$$2^{-n(H(X)+\delta)} \leq \prod_{i=1}^{N} p_{x_i} \leq 2^{-n(H(X)-\delta)}.$$

The set of all δ-weakly typical sequences is called the *δ-weakly typical set*, and is denoted by $\mathcal{T}_{n,\delta}$ in the following. Denoting $\prod_{i=1}^{N} p_{x_i}$ by $p_{\boldsymbol{x}}$, we have

$$1 = \sum_{\boldsymbol{x}\in\mathcal{X}^n} p_{\boldsymbol{x}} \geq \sum_{\boldsymbol{x}\in\mathcal{T}_{n,\delta}} p_{\boldsymbol{x}} \geq |\mathcal{T}_{n,\delta}| \cdot 2^{-n(H(X)+\delta)},$$

which implies that

$$|\mathcal{T}_{n,\delta}| \leq 2^{n(H(X)+\delta)}. \tag{50}$$

A sequence $\boldsymbol{x} = (x_1, \cdots, x_n) \in \mathcal{X}^n$ is called *δ-strongly typical with respect to $\{p_x\}_{x\in\mathcal{X}}$* if it satisfies

$$\left|\frac{1}{n}N_{x|\boldsymbol{x}} - p_x\right| < \frac{\delta}{|\mathcal{X}|}$$

for all $x \in \mathcal{X}$ and $N_{x|\boldsymbol{x}} = 0$ if $p_x = 0$. Here, $N_{x|\boldsymbol{x}}$ is the number of occurrences of the symbol x in the sequence $\boldsymbol{x}$. The set of all δ-strongly typical sequences is called the *δ-strongly typical set*, and denoted by $\mathcal{T}^*_{n,\delta}$ in the following. From the weak law of large numbers, we have that for any $\epsilon, \delta > 0$ and sufficiently large n,

$$\Pr\{(X_1, \cdots, X_n) \in \mathcal{T}_{n,\delta}\} \geq 1 - \epsilon, \tag{51}$$
$$\Pr\{(X_1, \cdots, X_n) \in \mathcal{T}^*_{n,\delta}\} \geq 1 - \epsilon. \tag{52}$$

Suppose the spectral decomposition of $\rho \in \mathcal{S}(\mathcal{H})$ is given by $\rho = \sum_x p_x |x\rangle\langle x|$. The δ-weakly typical subspace $\mathcal{H}_{n,\delta} \subset \mathcal{H}^{\otimes n}$ with respect to ρ is defined as

$$\mathcal{H}_{n,\delta} := \mathrm{span}\{|x_1\rangle \cdots |x_n\rangle \in \mathcal{H}^{\otimes n} | (x_1, \cdots, x_n) \in \mathcal{T}_{n,\delta}\},$$

where $\mathcal{T}_{n,\delta}$ is the δ-weakly typical set with respect to p_x. Similarly, the δ-strongly typical subspace $\mathcal{H}^*_{n,\delta} \subset \mathcal{H}^{\otimes n}$ with respect to ρ is defined as

$$\mathcal{H}^*_{n,\delta} := \mathrm{span}\{|x_1\rangle \cdots |x_n\rangle \in \mathcal{H}^{\otimes n} | (x_1, \cdots, x_n) \in \mathcal{T}^*_{n,\delta}\}.$$

Suppose the Schmidt decomposition of $|\psi\rangle^{AB} \in \mathcal{H}^A \otimes \mathcal{H}^B$ is given by $|\psi\rangle^{AB} = \sum_x \sqrt{p_x}|x\rangle^A|x\rangle^B$. For any $\delta > 0$ and n, let $\mathcal{H}_{n,\delta}$ and $\mathcal{H}^*_{n,\delta}$ be the δ-weakly and strongly typical subspace of $(\mathcal{H}^A)^{\otimes n}$ with respect to $\psi^A = \mathrm{Tr}_B[|\psi\rangle\langle\psi|^{AB}]$, and let $\Pi_{n,\delta}$ and $\Pi^*_{n,\delta}$ be the projection onto those subspaces, respectively. From (50), we have

$$\mathrm{rank}\,\Pi_{n,\delta} = \dim \mathcal{H}_{n,\delta} \leq 2^{n(H(A)_\psi+\delta)}.$$

From (51) and (52), we have

$$\mathrm{Tr}[\Pi^{\bar{A}}_{n,\delta}(|\psi\rangle\langle\psi|^{AB})^{\otimes n}] = \sum_{\boldsymbol{x}\in\mathcal{T}_{n,\delta}} p_{\boldsymbol{x}} \geq 1 - \epsilon, \tag{53}$$

$$\mathrm{Tr}[\Pi^{*\bar{A}}_{n,\delta}(|\psi\rangle\langle\psi|^{AB})^{\otimes n}] = \sum_{\boldsymbol{x}\in\mathcal{T}^*_{n,\delta}} p_{\boldsymbol{x}} \geq 1 - \epsilon \tag{54}$$

for any $\epsilon, \delta > 0$ and sufficiently large n.

APPENDIX B
PROOF OF THEOREM 9

In this Appendix, we show a detailed proof of Theorem 9. In the following, we informally denote the composite systems $a_0a_La_R$ by A and $b_0b_Lb_R$ by B, when there is no fear of confusion.

A. *Proof of Achievability (Inequality (16))*

Fix arbitrary n and $\delta \in (0, 1]$. Let $J_{n,\delta} \subset J^n$ be the δ-strongly typical set with respect to $\{p_j\}_{j\in J}$. For each $j \in J$ and $\boldsymbol{j} = j_1 \cdots j_n \in J_{n,\delta}$, define $\mathfrak{L}_{j,\boldsymbol{j}} := \{l | j_l = j, 1 \leq l \leq n\}$. The number of elements in the set is bounded as

$$n\left(p_j - \frac{\delta}{|J|}\right) \leq |\mathfrak{L}_{j,\boldsymbol{j}}| \leq n\left(p_j + \frac{\delta}{|J|}\right).$$

For each $\boldsymbol{j} \in J_{n,\delta}$, we sort $(\mathcal{H}^{a_R})^{\otimes n} = \mathcal{H}^{a_{R_1}} \otimes \cdots \otimes \mathcal{H}^{a_{R_n}}$ as

$$(\mathcal{H}^{a_R})^{\otimes n} = \bigotimes_{j\in J}\left(\bigotimes_{l\in\mathfrak{L}_{j,\boldsymbol{j}}} \mathcal{H}^{a_{R_l}}\right).$$

For each j and $\boldsymbol{j}$, let $\mathcal{H}_{j,\boldsymbol{j},\delta}$ be the δ-weakly typical subspace of $\bigotimes_{l\in\mathfrak{L}_{j,\boldsymbol{j}}} \mathcal{H}^{a_{R_l}}$ with respect to $\varphi_j^{a_R}$, $\Pi_{j,\boldsymbol{j},\delta}$ be the projection onto $\mathcal{H}_{j,\boldsymbol{j},\delta}$, and let $\Pi^{\bar{a}_R}_{\boldsymbol{j},\delta} := \bigotimes_{j\in J} \Pi_{j,\boldsymbol{j},\delta}$. Define

$$\Pi^{\bar{A}}_{\delta} := \sum_{\boldsymbol{j}\in J_{n,\delta}} |\boldsymbol{j}\rangle\langle\boldsymbol{j}|^{\bar{a}_0} \otimes I^{\bar{a}_L}_{\boldsymbol{j}} \otimes \Pi^{\bar{a}_R}_{\boldsymbol{j},\delta} \tag{55}$$

and

$$\begin{aligned}|\Psi'_{n,\delta}\rangle^{\bar{A}\bar{B}\bar{C}} &:= \Pi^{\bar{A}}_{\delta}|\Psi^{\otimes n}_{KI}\rangle^{\bar{A}\bar{B}\bar{C}} \\ &= \sum_{\boldsymbol{j}\in J_{n,\delta}} \sqrt{p_{\boldsymbol{j}}}|\boldsymbol{j}\rangle^{\bar{a}_0}|\boldsymbol{j}\rangle^{\bar{b}_0}|\omega_{\boldsymbol{j}}\rangle^{\bar{a}_L\bar{b}_L}\Pi^{\bar{a}_R}_{\boldsymbol{j},\delta}|\varphi_{\boldsymbol{j}}\rangle^{\bar{a}_R\bar{b}_R\bar{C}},\end{aligned} \tag{56}$$

where we introduced notations $p_{\boldsymbol{j}} = p_{j_1} \times \cdots \times p_{j_n}$, $\varphi_{\boldsymbol{j}} = \varphi_{j_1} \otimes \cdots \otimes \varphi_{j_n}$ and $\omega_{\boldsymbol{j}} = \omega_{j_1} \otimes \cdots \otimes \omega_{j_n}$.

Let $v_{\boldsymbol{j}}$ be any unitary acting on $\bigotimes_{j\in J} \mathcal{H}_{j,\boldsymbol{j}}$, and define a unitary on $\bigotimes_{\boldsymbol{j}\in J_{n,\delta}}(\bigotimes_{j\in J} \mathcal{H}_{j,\boldsymbol{j}})$ by

$$V^{\bar{A}} := \sum_{\boldsymbol{j}\in J_{n,\delta}} |\boldsymbol{j}\rangle\langle\boldsymbol{j}|^{\bar{a}_0} \otimes I^{\bar{a}_L}_{\boldsymbol{j}} \otimes v^{\bar{a}_R}_{\boldsymbol{j}}, \tag{57}$$

as (18). We have

$$\begin{aligned}|\Psi'_{n,\delta}(V)\rangle^{\bar{A}\bar{B}\bar{C}} &:= V^{\bar{A}}|\Psi'_{n,\delta}\rangle^{\bar{A}\bar{B}\bar{C}} \\ &= \sum_{\boldsymbol{j}\in J_{n,\delta}} \sqrt{p_{\boldsymbol{j}}}|\boldsymbol{j}\rangle^{\bar{a}_0}|\boldsymbol{j}\rangle^{\bar{b}_0}|\omega_{\boldsymbol{j}}\rangle^{\bar{a}_L\bar{b}_L}v^{\bar{a}_R}_{\boldsymbol{j}}|\varphi'_{\boldsymbol{j}}\rangle^{\bar{a}_R\bar{b}_R\bar{C}},\end{aligned} \tag{58}$$

where $|\varphi'_{\boldsymbol{j}}\rangle := \Pi^{\bar{a}_R}_{\boldsymbol{j}}|\varphi_{\boldsymbol{j}}\rangle$.

Let $\{p(dV), V\}$ be the ensemble of unitaries generated by choosing $v_{\boldsymbol{j}}$ randomly and independently according to the Haar measure for each $\boldsymbol{j}$ in (57). Due to Schur's lemma, as an ensemble average we have

$$\mathbb{E}\left[v^{\bar{a}_R}_{\boldsymbol{j}}|\varphi'_{\boldsymbol{j}}\rangle\langle\varphi'_{\boldsymbol{j}}|v^{\dagger\bar{a}_R}_{\boldsymbol{j}}\right] = \pi^{\bar{a}_R}_{\boldsymbol{j}} \otimes \varphi'^{\bar{b}_R\bar{C}}_{\boldsymbol{j}},$$

where $\pi^{\bar{a}_R}_{\boldsymbol{j}} = \Pi^{\bar{a}_R}_{\boldsymbol{j},\delta}/\mathrm{Tr}\Pi^{\bar{a}_R}_{\boldsymbol{j},\delta}$, and

$$\mathbb{E}\left[v^{\bar{a}_R}_{\boldsymbol{j}}|\varphi'_{\boldsymbol{j}}\rangle\langle\varphi'_{\boldsymbol{j}'}|v^{\dagger\bar{a}_R}_{\boldsymbol{j}'}\right] = 0$$

for $\boldsymbol{j} \neq \boldsymbol{j}'$. Thus the average state of (58) is given by

$$\begin{aligned}\bar{\Psi}_{n,\delta} &:= \mathbb{E}\left[|\Psi'_{n,\delta}(V)\rangle\langle\Psi'_{n,\delta}(V)|^{\bar{A}\bar{B}\bar{C}}\right] \\ &= \sum_{\boldsymbol{j}\in J_{n,\delta}} p_{\boldsymbol{j}}|\boldsymbol{j}\boldsymbol{j}\rangle\langle\boldsymbol{j}\boldsymbol{j}|^{\bar{a}_0\bar{b}_0}\otimes|\omega_{\boldsymbol{j}}\rangle\langle\omega_{\boldsymbol{j}}|^{\bar{a}_L\bar{b}_L} \otimes \pi^{\bar{a}_R}_{\boldsymbol{j}} \otimes \varphi'^{\bar{b}_R\bar{C}}_{\boldsymbol{j}} \\ &= \sum_{\boldsymbol{j}\in J_{n,\delta}} p_{\boldsymbol{j}}|\boldsymbol{j}\rangle\langle\boldsymbol{j}|^{\bar{b}_0}\otimes\left(\pi^{\bar{a}_R}_{\boldsymbol{j}}\otimes|\boldsymbol{j},\omega_{\boldsymbol{j}}\rangle\langle\boldsymbol{j},\omega_{\boldsymbol{j}}|^{\bar{a}_0\bar{a}_L\bar{b}_L}\right) \otimes \varphi'^{\bar{b}_R\bar{C}}_{\boldsymbol{j}},\end{aligned} \tag{59}$$

which is a subnormalized Markov state conditioned by $\bar{B}$ corresponding to (19) (see Figure 3).

The minimum nonzero eigenvalue of $\bar{\Psi}_{n,\delta}$ is calculated as follows. First, due to the definition of $J_{n,\delta}$, we have

$$p_{\boldsymbol{j}} \geq \prod_{j\in J} p_j^{n(p_j+\delta/|J|)} = 2^{-n\left(H(\{p_j\}_j)+\delta H'(\{p_j\}_j)\right)},$$

where

$$H'(\{p_j\}_j) := \frac{1}{|J|}\sum_j \log p_j > -\infty.$$

Second, since the spectrums of $\varphi_{\boldsymbol{j}}^{\prime\bar{a}_R}$ and $\varphi_{\boldsymbol{j}}^{\prime\bar{b}_R\bar{C}}$ are the same, the minimum nonzero eigenvalue $\mu_{\boldsymbol{j}}$ of $\varphi_{\boldsymbol{j}}^{\prime\bar{b}_R\bar{C}}$ is bounded from below as

$$\begin{aligned}
\mu_{\boldsymbol{j}} &\geq \prod_{j\in J} 2^{-\mathfrak{L}_{j,\boldsymbol{j}}(S(\varphi_j^{a_R})+\delta)} \\
&\geq \prod_{j\in J} 2^{-n(p_j+\delta/|J|)(S(\varphi_j^{a_R})+\delta)} \\
&\geq 2^{-n\left(\sum_j p_j S(\varphi_j^{a_R})+\delta\log(4d_A)\right)},
\end{aligned}$$

where the last line follows from

$$\begin{aligned}
&\sum_j \left(p_j+\frac{\delta}{|J|}\right)\left(S(\varphi_j^{a_R})+\delta\right) \\
&= \sum_j p_j S(\varphi_j^{a_R}) + \delta\left(1+\frac{1}{|J|}\sum_j S(\varphi_j^{a_R})+\delta\right) \\
&\leq \sum_j p_j S(\varphi_j^{a_R}) + \delta\left(2+\log d_A\right) \\
&= \sum_j p_j S(\varphi_j^{a_R}) + \delta\log(4d_A).
\end{aligned}$$

Third, we have

$$\operatorname{rank}\Pi_{j,\boldsymbol{j},\delta} \leq 2^{|\mathfrak{L}_{j,\boldsymbol{j}}|(S(\varphi_j^{a_R})+\delta)} \leq 2^{n(p_j+\delta/|J|)(S(\varphi_j^{a_R})+\delta)}$$

and

$$\operatorname{rank}\Pi_{\boldsymbol{j},\delta}^{\bar{a}_R} = \prod_{j\in J}\operatorname{rank}\Pi_{j,\boldsymbol{j},\delta} \leq \prod_{j\in J} 2^{n(p_j+\delta/|J|)(S(\varphi_j^{a_R})+\delta)}.$$

Thus the nonzero eigenvalue $\nu_{\boldsymbol{j}}$ of $\pi_{\boldsymbol{j}}^{\bar{a}_R}$ is, in the same way as $\mu_{\boldsymbol{j}}$, bounded from below as

$$\nu_{\boldsymbol{j}} \geq \prod_{j\in J} 2^{-n(p_j+\delta/|J|)(S(\varphi_j^{a_R})+\delta)}.$$

All in all, the minimum nonzero eigenvalue λ of $\bar{\Psi}_{n,\delta}$ is bounded as

$$\begin{aligned}
\lambda &= p_{\boldsymbol{j}}\mu_{\boldsymbol{j}}\nu_{\boldsymbol{j}} \\
&\geq 2^{-n\left[H(\{p_j\}_j)+2\sum_j p_j S(\varphi_j^{a_R})+\delta\left(H'(\{p_j\}_j)+2\log(4d_A)\right)\right]}.
\end{aligned}$$

We also have

$$\operatorname{rank}\bar{\Psi}_{n,\delta} \leq |J_{n,\delta}| \times \operatorname{rank}\pi_{\boldsymbol{j}}^{\bar{a}_R} \times \operatorname{rank}\varphi_{\boldsymbol{j}}^{\prime\bar{a}_R} \leq d_A^{3n}.$$

Suppose $V_1,\cdots,V_N$ are unitaries that are randomly and independently chosen from the ensemble $\{p(dV),V\}$. Due to the operator Chernoff bound (Lemma 3 in [11]), we have

$$\begin{aligned}
&\Pr\left\{\frac{1}{N}\sum_{i=1}^N \Psi'_{n,\delta}(V_i) \notin [(1-\epsilon_1)\bar{\Psi}_{n,\delta},(1+\epsilon_1)\bar{\Psi}_{n,\delta}]\right\} \\
&\leq 2d_A^{3n}\exp\left(-\frac{N\lambda\epsilon_1^2}{2}\right)
\end{aligned}$$

for any $\epsilon_1 \in (0,1]$, which implies that

$$\begin{aligned}
&\Pr\left\{\left\|\frac{1}{2^{nR}}\sum_{i=1}^{2^{nR}}\Psi'_{n,\delta}(V_i)-\bar{\Psi}_{n,\delta}\right\|_1 \leq 2\epsilon_1\right\} \\
&\geq 1-2d_A^{3n}\exp\left(-\frac{2^{nR}\lambda\epsilon_1^2}{2}\right) \qquad (60)
\end{aligned}$$

for an arbitrary $R>0$. Therefore, if R satisfies

$$\begin{aligned}
R > {}&H(\{p_j\}_j)+2\sum_j p_j S(\varphi_j^{a_R}) \\
&+\delta\left(H'(\{p_j\}_j)+2\log(4d_A)\right), \qquad (61)
\end{aligned}$$

and if n is sufficiently large so that the R.H.S. in (60) is greater than 0, there exists a set of unitaries $\{V_i\}_{i=1}^{2^{nR}}$ such that

$$\left\|\frac{1}{2^{nR}}\sum_{i=1}^{2^{nR}}\Psi'_{n,\delta}(V_i)-\bar{\Psi}_{n,\delta}\right\|_1 \leq 2\epsilon_1. \qquad (62)$$

Using unitaries in the set, construct a random unitary operation $\mathcal{V}_n$ on $\hat{a}_0\hat{a}_L\hat{a}_R$ as $\mathcal{V}_n(\cdot)=2^{-nR}\sum_{k=1}^{2^{nR}}V_k(\cdot)V_k^\dagger$.

Let us evaluate the total error. First, from (53), (54), (55) and (56), we have

$$D_{n,\delta} := \mathrm{Tr}[\Pi_\delta^{\bar{A}}|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|] = \langle\Psi'_{n,\delta}|\Psi'_{n,\delta}\rangle \geq 1-\epsilon_2 \qquad (63)$$

for any $\epsilon_2>0$ and sufficiently large n. Thus, by the gentle measurement lemma (40), we have

$$\left\|\frac{|\Psi'_{n,\delta}\rangle\langle\Psi'_{n,\delta}|}{D_{n,\delta}}-|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|\right\|_1 \leq 2\sqrt{\epsilon_2},$$

which leads to

$$\left\|\mathcal{V}_n\left(\frac{|\Psi'_{n,\delta}\rangle\langle\Psi'_{n,\delta}|}{D_{n,\delta}}\right)-\mathcal{V}_n\left(|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|\right)\right\|_1 \leq 2\sqrt{\epsilon_2}.$$

Second, from (62) and (63), we have

$$\left\|\mathcal{V}_n\left(\frac{|\Psi'_{n,\delta}\rangle\langle\Psi'_{n,\delta}|}{D_{n,\delta}}\right)-\frac{\bar{\Psi}_{n,\delta}}{D_{n,\delta}}\right\|_1 \leq \frac{2\epsilon_1}{D_{n,\delta}} \leq \frac{2\epsilon_1}{1-\epsilon_2}.$$

Therefore, by the triangle inequality, we obtain

$$\left\|\mathcal{V}_n\left(|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|\right)-\frac{\bar{\Psi}_{n,\delta}}{D_{n,\delta}}\right\|_1 \leq 2\sqrt{\epsilon_2}+\frac{2\epsilon_1}{1-\epsilon_2}. \qquad (64)$$

From (58) and (59), we have $\mathrm{Tr}[\bar{\Psi}_{n,\delta}]=D_{n,\delta}$, which implies that $\bar{\Psi}_{n,\delta}/D_{n,\delta}$ is a normalized Markov state conditioned by B^n. Since the relation (64) holds for any $\epsilon_1,\epsilon_2>0$, $R>H(\{p_j\}_j)+2\sum_j p_j S(\varphi_j^{a_R})$, any $\delta\in(0,1]$ that satisfies (61) and sufficiently large n, we obtain (16). ■

B. Convergence Speed of the Error

We prove that, in the direct part of Theorem 9, the error ϵ vanishes exponentially in the asymptotic limit of $n \to \infty$. More precisely, we prove the following theorem.

Theorem 14 There exists a constant $c_{\Psi} > 0$ such that for any $R > M_{A|B}(\Psi^{ABC})$, sufficiently small $\delta > 0$ and any sufficiently large n, we find a random unitary operation $\mathcal{V}_n : \tau \mapsto 2^{-nR} \sum_{k=1}^{2^{nR}} V_k \tau V_k^{\dagger}$ on A^n and a Markov state $\Upsilon^{A^n B^n C^n}$ conditioned by B^n that satisfy

$$\left\| \mathcal{V}_n(\rho^{\otimes n}) - \Upsilon^{A^n B^n C^n} \right\|_1 \leq 6 \exp\left(-\frac{c_{\Psi} \delta^2 n}{2} \right).$$

Proof: Let $X_1, \cdots, X_n$ be a sequence of i.i.d. random variables obeying a probability distribution $\{p_x\}_x$. It is proved in [35] that there exists a constant $c > 0$, which depends on $\{p_x\}_x$, such that for any $\delta > 0$ and n, we have

$$\Pr\{(X_1, \cdots, X_n) \in \mathcal{T}_{n,\delta}\} \geq 1 - \exp(-c\delta^2 n),$$
$$\Pr\{(X_1, \cdots, X_n) \in \mathcal{T}^*_{n,\delta}\} \geq 1 - \exp(-c\delta^2 n).$$

As a consequence, there exists a constant $c_{\psi} > 0$ such that we have

$$\mathrm{Tr}[\Pi_{n,\delta}(|\psi\rangle\langle\psi|^{AB})^{\otimes n}] = \sum_{\boldsymbol{x} \in \mathcal{T}_{n,\delta}} p_{\boldsymbol{x}} \geq 1 - \exp(-c_{\psi}\delta^2 n)$$
$$\mathrm{Tr}[\Pi^*_{n,\delta}(|\psi\rangle\langle\psi|^{AB})^{\otimes n}] = \sum_{\boldsymbol{x} \in \mathcal{T}^*_{n,\delta}} p_{\boldsymbol{x}} \geq 1 - \exp(-c_{\psi}\delta^2 n)$$

for any $\delta > 0$ and n, corresponding to (53) and (54). Thus, for any $\delta > 0$, n and $D_{n,\delta}$ defined by (63), we obtain

$$D_{n,\delta} \geq 1 - \exp(-c_{\Psi}\delta^2 n),$$

where $c_{\Psi} > 0$ is a constant. Hence we have

$$\begin{aligned} &\left\| \mathcal{V}_n\left(|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|\right) - \frac{\bar{\Psi}_{n,\delta}}{D_{n,\delta}} \right\|_1 \\ &\leq 2\exp\left(-\frac{c_{\Psi}\delta^2 n}{2}\right) + \frac{2\epsilon_1}{1 - \exp(-c_{\Psi}\delta^2 n)} \end{aligned}$$

for *any* $\delta, \epsilon_1 > 0$ and n, corresponding to (64). Substituting $\exp(-c_{\Psi}\delta^2 n/2)$ into ϵ_1, we obtain

$$\left\| \mathcal{V}_n\left(|\Psi_{KI}^{\otimes n}\rangle\langle\Psi_{KI}^{\otimes n}|\right) - \frac{\bar{\Psi}_{n,\delta}}{D_{n,\delta}} \right\|_1 \leq 6\exp\left(-\frac{c_{\Psi}\delta^2 n}{2}\right) \quad (65)$$

for any $\delta > 0$ and $n \geq (\ln 2)/c_{\Psi}\delta^2$.

For an arbitrary R, choose sufficiently small $\delta > 0$ such that

$$\begin{aligned} R > {} & H(\{p_j\}_j) + 2\sum_j p_j S(\varphi_j^{a_R}) \\ & + \delta\left(H'(\{p_j\}_j) + 2\log(4d_A) + c_{\Psi}\delta\right). \end{aligned}$$

Inequality (65) then holds for sufficiently large n, while keeping the R.H.S. in (60) strictly greater than 0. This completes the proof. ■

C. Proof of Optimality (Inequality (20))

We assume, without loss of generality, that $d_A \geq d_B d_C$. This condition is always satisfied by associating a sufficiently large Hilbert space $\mathcal{H}^A$ to system A.

Take an arbitrary $R > M_{A|B}(\Psi^{ABC})$. By definition, for any $\epsilon \in (0,1]$ and sufficiently large n, there exist a random unitary operation $\mathcal{V}_n : \tau \mapsto 2^{-nR} \sum_{k=1}^{2^{nR}} V_k \tau V_k^{\dagger}$ on $\bar{A}$ and a Markov state $\Upsilon^{\bar{A}\bar{B}\bar{C}}$ conditioned by $\bar{B}$ such that

$$\left\| \mathcal{V}_n(\Psi^{\otimes n}) - \Upsilon^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq \epsilon. \quad (66)$$

By tracing out A^n, we have

$$\left\| (\Psi^{\otimes n})^{\bar{B}\bar{C}} - \Upsilon^{\bar{B}\bar{C}} \right\|_1 \leq \epsilon. \quad (67)$$

Due to Uhlmann's theorem ([24], see Appendix A-A), there exists a purification $|\chi\rangle^{\bar{A}\bar{B}\bar{C}}$ of $\Upsilon^{\bar{B}\bar{C}}$ such that we have

$$\left\| (\Psi^{\otimes n})^{\bar{A}\bar{B}\bar{C}} - \chi^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq 2\sqrt{\epsilon}. \quad (68)$$

Let $\tilde{\Gamma}' : \mathcal{H}_{\chi}^{\bar{B}} \to \mathcal{H}^{\hat{b}_0} \otimes \mathcal{H}^{\hat{b}_L} \otimes \mathcal{H}^{\hat{b}_R}$ be the KI isometry on $\bar{B}$ with respect to $\chi^{\bar{B}\bar{C}}$. From Lemma 11, there exists a sub-KI isometry $\tilde{\Gamma} : \mathcal{H}_{\chi}^{\bar{A}} \to \mathcal{H}^{\hat{a}_0} \otimes \mathcal{H}^{\hat{a}_L} \otimes \mathcal{H}^{\hat{a}_R}$ such that the KI decomposition of $|\chi\rangle$ on $\bar{B}$ and $\bar{A}$ is given by

$$\begin{aligned} |\chi_{KI}\rangle &:= (\tilde{\Gamma}^{\bar{A}} \otimes \tilde{\Gamma}'^{\bar{B}})|\chi\rangle \\ &= \sum_i \sqrt{q_i}|i\rangle^{\hat{a}_0}|i\rangle^{\hat{b}_0}|\xi_i\rangle^{\hat{a}_L\hat{b}_L}|\phi_i\rangle^{\hat{a}_R\hat{b}_R\bar{C}}. \end{aligned} \quad (69)$$

From Theorem 7 and $\chi^{\bar{B}\bar{C}} = \Upsilon^{\bar{B}\bar{C}}$, a Markov decomposition of $\Upsilon^{\bar{A}\bar{B}\bar{C}}$ is obtained by $\tilde{\Gamma}'$ as

$$\Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}} := \tilde{\Gamma}'^{\bar{B}} \Upsilon'^{\bar{A}\bar{B}\bar{C}} \tilde{\Gamma}'^{\dagger\bar{B}} = \sum_i q_i |i\rangle\langle i|^{\hat{b}_0} \otimes \sigma_i^{\bar{A}\hat{b}_L} \otimes \phi_i^{\hat{b}_R\bar{C}}. \quad (70)$$

Due to (68) and the monotonicity of the trace distance, we have

$$\left\| \mathcal{V}_n(\Psi^{\otimes n}) - \mathcal{V}_n(\chi^{\bar{A}\bar{B}\bar{C}}) \right\|_1 \leq 2\sqrt{\epsilon}.$$

Thus from (66) and the triangle inequality, we obtain

$$\left\| \mathcal{V}_n(\chi^{\bar{A}\bar{B}\bar{C}}) - \Upsilon^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq 2\sqrt{\epsilon} + \epsilon < 3\sqrt{\epsilon}.$$

Applying $\tilde{\Gamma}'^{\bar{B}}$ yields

$$\left\| \mathcal{V}_n\left(\tilde{\Gamma}'^{\bar{B}} \chi^{\bar{A}\bar{B}\bar{C}} \tilde{\Gamma}'^{\dagger\bar{B}}\right) - \Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq 3\sqrt{\epsilon},$$

due to (70). Hence we obtain from (69) that

$$\left\| \mathcal{V}_n\left(\tilde{\Gamma}^{\dagger\bar{A}} \chi_{KI}^{\bar{A}\bar{B}\bar{C}} \tilde{\Gamma}^{\bar{A}}\right) - \Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq 3\sqrt{\epsilon}. \quad (71)$$

Let $\mathcal{D}^{\hat{b}_0}$ be the completely dephasing operation on $\hat{b}_0$ with respect to the basis $\{|i\rangle^{\hat{b}_0}\}_i$. From (70), we have $\mathcal{D}^{\hat{b}_0}(\Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}}) = \Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}}$. Thus we obtain from (71) that

$$\left\| (\mathcal{T}'_n \otimes \mathcal{D}^{\hat{b}_0})(|\chi_{KI}\rangle\langle\chi_{KI}|) - \Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}} \right\|_1 \leq 3\sqrt{\epsilon}. \quad (72)$$

Here, we defined a random isometry operation $\mathcal{T}'_n := \mathcal{V}_n \circ \mathcal{E}_{\tilde{\Gamma}^{\dagger}}$, where $\mathcal{E}_{\tilde{\Gamma}^{\dagger}}$ is an isometry operation corresponding to $\tilde{\Gamma}^{\dagger}$.

Due to (69), we have

$$\begin{aligned}&\mathcal{D}^{\hat{b}_0}(|\chi_{KI}\rangle\langle\chi_{KI}|)\\&=\sum_i q_i|i\rangle\langle i|^{\hat{a}_0}\otimes|i\rangle\langle i|^{\hat{b}_0}\otimes|\xi_i\rangle\langle\xi_i|^{\hat{a}_L\hat{b}_L}\otimes|\phi_i\rangle\langle\phi_i|^{\hat{a}_R\hat{b}_R\bar{C}},\end{aligned}$$

which leads to

$$\begin{aligned}&\mathrm{Tr}_{\hat{b}_R\bar{C}}\left[\mathcal{D}^{\hat{b}_0}(|\chi_{KI}\rangle\langle\chi_{KI}|)\right]\\&=\sum_i q_i|i\rangle\langle i|^{\hat{b}_0}\otimes|i,\xi_i\rangle\langle i,\xi_i|^{\hat{a}_0\hat{a}_L\hat{b}_L}\otimes\phi_i^{\hat{a}_R}.\end{aligned}$$

Hence we have

$$\mathrm{Tr}_{\hat{b}_R\bar{C}}\left[(\mathcal{T}_n'\otimes\mathcal{D}^{\hat{b}_0})(|\chi_{KI}\rangle\langle\chi_{KI}|)\right]=\sum_i q_i|i\rangle\langle i|^{\hat{b}_0}\otimes\phi_{i,\mathcal{T}_n'}^{\bar{A}\hat{b}_L},$$

where we define

$$\phi_{i,\mathcal{T}_n'}^{\bar{A}\hat{b}_L}:=\mathcal{T}_n'(|i,\xi_i\rangle\langle i,\xi_i|^{\hat{a}_0\hat{a}_L\hat{b}_L}\otimes\phi_i^{\hat{a}_R}). \tag{73}$$

From (70) we have

$$\mathrm{Tr}_{\hat{b}_R\bar{C}}\left[\Upsilon_{Mk}^{\bar{A}\bar{B}\bar{C}}\right]=\sum_i q_i|i\rangle\langle i|^{\hat{b}_0}\otimes\sigma_i^{\bar{A}\hat{b}_L}.$$

Therefore, by tracing out $\hat{b}_R\bar{C}$ in (72), we obtain

$$\left\|\sum_i q_i|i\rangle\langle i|^{\hat{b}_0}\otimes\phi_{i,\mathcal{T}_n'}^{\bar{A}\hat{b}_L}-\sum_i q_i|i\rangle\langle i|^{\hat{b}_0}\otimes\sigma_i^{\bar{A}\hat{b}_L}\right\|_1\leq 3\sqrt{\epsilon}.$$

Thus, by Inequality (47), we have

$$\begin{aligned}&H(\{q_i\}_i)+\sum_i q_i S(\sigma_i^{\bar{A}\hat{b}_L})\\&\geq H(\{q_i\}_i)+\sum_i q_i S(\phi_{i,\mathcal{T}_n'}^{\bar{A}\hat{b}_L})-\eta(3\sqrt{\epsilon})\log(d_{\bar{A}}d_{\bar{B}}).\end{aligned}$$

Since the von Neumann entropy is nondecreasing under random unitary operations, we have $S(\phi_{i,\mathcal{T}_n'}^{\bar{A}\hat{b}_L})\geq S(\phi_i^{\hat{a}_R})$ for each j from (73). Hence we obtain

$$\sum_i q_i S(\sigma_i^{\bar{A}\hat{b}_L})\geq\sum_i q_i S(\phi_i^{\hat{a}_R})-\eta(3\sqrt{\epsilon})\log(d_{\bar{A}}d_{\bar{B}}). \tag{74}$$

The von Neumann entropy of the state $\Upsilon^{\bar{A}\bar{B}\bar{C}}$ is then bounded below as

$$\begin{aligned}&S(\bar{A}\bar{B}\bar{C})_\Upsilon=S(\bar{A}\hat{b}_0\hat{b}_L\hat{b}_R\bar{C})_{\Upsilon_{Mk}}\\&=S(\hat{b}_0)_{\Upsilon_{Mk}}+S(\bar{A}\hat{b}_L\hat{b}_R\bar{C}|\hat{b}_0)_{\Upsilon_{Mk}}\\&=H(\{q_i\}_i)+\sum_i q_i(S(\sigma_i^{\bar{A}\hat{b}_L})+S(\phi_i^{\hat{b}_R\bar{C}}))\\&=H(\{q_i\}_i)+\sum_i q_i(S(\sigma_i^{\bar{A}\hat{b}_L})+S(\phi_i^{\hat{a}_R}))\\&\geq H(\{q_i\}_i)+2\sum_i q_i S(\phi_i^{\hat{a}_R})-n\eta(3\sqrt{\epsilon})\log(d_Ad_Bd_C)\\&=S(\hat{a}_0)_{\chi_{KI}}+2S(\hat{a}_R|\hat{a}_0)_{\chi_{KI}}-n\eta(3\sqrt{\epsilon})\log(d_Ad_Bd_C).\end{aligned} \tag{75}$$

Here, the third line follows from (70); the fourth line because of $\phi_i^{\hat{a}_R\hat{b}_R\bar{C}}$ being a pure state; the fifth line by Inequality (74); and the sixth line from (69). From Lemma 12, (68) implies

$$\begin{aligned}&S(\hat{a}_0)_{\chi_{KI}}+2S(\hat{a}_R|\hat{a}_0)_{\chi_{KI}}\\&\geq n\left(S(a_0)_{\Psi_{KI}}+2S(a_R|a_0)_{\Psi_{KI}}-\zeta_\Psi'(2\sqrt{\epsilon})\log d_A\right),\end{aligned} \tag{76}$$

where $\zeta_\Psi'(\epsilon)$ is a function defined by (90) in Appendix B-D. Putting together (75) and (76), we obtain

$$\begin{aligned}\frac{1}{n}S(\bar{A}\bar{B}\bar{C})_\Upsilon\ &\geq\ S(a_0)_{\Psi_{KI}}+2S(a_R|a_0)_{\Psi_{KI}}\\&\quad-\left(2\eta(3\sqrt{\epsilon})+\zeta_\Psi'(2\sqrt{\epsilon})\right)\log(d_Ad_Bd_C).\end{aligned}$$

Noting that $\mathcal{V}_n(\Psi^{\otimes n})$ is a mixture of 2^{nR} (not necessarily orthogonal) pure states, from (66), we finally obtain

$$\begin{aligned}R\ &\geq\ \frac{1}{n}S(\bar{A}\bar{B}\bar{C})_{\mathcal{V}_n(\Psi^{\otimes n})}\\&\geq\ \frac{1}{n}S(\bar{A}\bar{B}\bar{C})_\Upsilon-\eta(\epsilon)\log(d_Ad_Bd_C)\\&\geq\ S(a_0)_{\Psi_{KI}}+2S(a_R|a_0)_{\Psi_{KI}}\\&\quad-\left(3\eta(3\sqrt{\epsilon})+\zeta_\Psi'(2\sqrt{\epsilon})\right)\log(d_Ad_Bd_C)\\&=\ H(\{p_j\}_{j\in J})+2\sum_{j\in J}p_jS(\varphi_j^{a_R})\\&\quad-\left(3\eta(3\sqrt{\epsilon})+\zeta_\Psi'(2\sqrt{\epsilon})\right)\log(d_Ad_Bd_C),\end{aligned}$$

which implies (20) by taking the limit of $\epsilon\to 0$. ■

D. Proof of Lemma 12

The key idea for the proof of Lemma 12 is similar to the one used in [25]. Let $\psi^{AC'}$ be a state such that the KI isometry on A with respect to $\psi^{AC'}$ is the same as that with respect to Ψ^{AC}, and that it is decomposed as

$$\begin{aligned}\psi_{KI}^{AC'}\ &:=\ (\Gamma_\Psi^A\otimes\Gamma_\psi^{C'})\psi^{AC'}(\Gamma_\Psi^A\otimes\Gamma_\psi^{C'})^\dagger\\&=\ \sum_{j\in J}p_j|j\rangle\langle j|^{a_0}\otimes\omega_j^{a_L}\otimes|\tilde{\varphi}_j\rangle\langle\tilde{\varphi}_j|^{a_Rc_R'}\otimes|j\rangle\langle j|^{c_0'},\end{aligned} \tag{77}$$

where $\Gamma_\psi:\mathcal{H}^{C'}\to\mathcal{H}^{c_0'}\otimes\mathcal{H}^{c_R'}$ is an isometry and $|\tilde{\varphi}_j\rangle^{a_Rc_R'}$ is a purification of $\varphi_j^{a_R}$. The state satisfies $\psi^A=\Psi^A$. Note that we have

$$d_{C'}=\sum_j\mathrm{rank}\,\tilde{\varphi}_j^{c_R'}=\sum_j\mathrm{rank}\,\tilde{\varphi}_j^{a_R}\leq d_A.$$

Let $\mathfrak{E}$ be the set of all linear CPTP maps on $\mathcal{S}(\mathcal{H}^A)$, and define two functions $f,g:\mathfrak{E}\to\mathbb{R}$ by

$$\begin{aligned}f(\mathcal{E})&=\left\|\mathcal{E}(\Psi^{AC})-\Psi^{AC}\right\|_1,\\g(\mathcal{E})&=\left\|\mathcal{E}(\psi^{AC'})-\psi^{AC'}\right\|_1.\end{aligned}$$

Since the KI decomposition of A with respect to Ψ^{AC} and that with respect to $\psi^{AC'}$ are the same, $f(\mathcal{E})=0$ if and only if $g(\mathcal{E})=0$ (see Lemma 5). Define

$$\zeta_\Psi(\epsilon):=\sup_{\mathcal{E}\in\mathfrak{E}}\{g(\mathcal{E})|f(\mathcal{E})\leq\epsilon\}. \tag{78}$$

This is a monotonically nondecreasing function of ϵ by definition, and satisfies $\lim_{\epsilon\to 0}\zeta_\Psi(\epsilon)=0$ as we prove in Appendix B-E.

We consider a general situation in which the relation (24) does not necessarily hold. Let Π_χ be the projection onto $\mathcal{H}_\chi^{\bar{A}}\subseteq\mathcal{H}^{\bar{A}}$, and $\Pi_\chi^\perp$ be that onto its orthogonal complement. Using a quantum channel $\mathcal{E}_\chi$ on $\mathcal{S}(\mathcal{H}_\chi^{\bar{A}})$ defined by (26), construct another quantum channel $\mathcal{E}_\chi^*$ on $\mathcal{S}(\mathcal{H}^{\bar{A}})$ by

$$\mathcal{E}_\chi^*(\tau)=\mathcal{E}_\chi(\Pi_\chi\tau\Pi_\chi)+\Pi_\chi^\perp\tau\Pi_\chi^\perp\quad(\forall\tau\in\mathcal{S}(\mathcal{H}^{\bar{A}})). \tag{79}$$

Define quantum channels $\mathcal{E}_l$ on A_l $(1 \leq l \leq n)$ by

$$\begin{aligned}\mathcal{E}_l(\tau^{A_l}) = \mathrm{Tr}_{\bar{A}\backslash A_l}\big[\mathcal{E}_\chi^*\big(\Psi^{A_1} \otimes \cdots \otimes \Psi^{A_{l-1}} \otimes \tau^{A_l} \\ \otimes \Psi^{A_{l+1}} \otimes \cdots \otimes \Psi^{A_n}\big)\big],\end{aligned}$$

where $\mathrm{Tr}_{\bar{A}\backslash A_l}$ denotes the partial trace over $A_1 \cdots A_{l-1}A_{l+1} \cdots A_n$. From (25), we have $\mathcal{E}_\chi^*(\chi^{\bar{A}\bar{C}}) = \mathcal{E}_\chi(\chi^{\bar{A}\bar{C}}) = \chi^{\bar{A}\bar{C}}$, and thus from (22) and the triangle inequality, we have

$$\left\|\mathcal{E}_\chi^*(\Psi^{\otimes n})^{\bar{A}\bar{C}} - (\Psi^{\otimes n})^{\bar{A}\bar{C}}\right\|_1 \leq 2\epsilon,$$

which implies

$$\left\|\mathcal{E}_l(\Psi^{A_lC_l}) - \Psi^{A_lC_l}\right\|_1 \leq 2\epsilon$$

by taking the partial trace. Thus we have

$$\left\|\mathcal{E}_l(\psi^{A_lC_l'}) - \psi^{A_lC_l'}\right\|_1 \leq \zeta_\Psi(2\epsilon)$$

for any $1 \leq l \leq n$. By Inequality (49) and $d_{C'} \leq d_A$, it follows that

$$I(A:C')_\psi - I(A_l:C_l')_{\mathcal{E}_l(\psi)} \leq 4\eta(\zeta_\Psi(2\epsilon))\log d_A,$$

and consequently, that

$$nI(A:C')_\psi - \sum_{l=1}^n I(A_l:C_l')_{\mathcal{E}_l(\psi)} \leq 4n\eta(\zeta_\Psi(2\epsilon))\log d_A. \tag{80}$$

We also have

$$\begin{aligned}& I(\bar{A}:\bar{C}')_{\mathcal{E}_\chi^*(\psi^{\otimes n})} = S(\bar{C}')_{\mathcal{E}_\chi^*(\psi^{\otimes n})} - S(\bar{C}'|\bar{A})_{\mathcal{E}_\chi^*(\psi^{\otimes n})} \\ &= S(\bar{C}')_{\psi^{\otimes n}} - \sum_{l=1}^n S(C_l'|A_1 \cdots A_n C_1' \cdots C_{l-1}')_{\mathcal{E}_\chi^*(\psi^{\otimes n})} \\ &\geq \sum_{l=1}^n S(C_l')_\psi - \sum_{l=1}^n S(C_l'|A_l)_{\mathcal{E}_\chi^*(\psi^{\otimes n})} \\ &= \sum_{l=1}^n S(C_l')_{\mathcal{E}_l(\psi)} - \sum_{l=1}^n S(C_l'|A_l)_{\mathcal{E}_l(\psi)} \\ &= \sum_{l=1}^n I(A_l:C_l')_{\mathcal{E}_l(\psi)}.\end{aligned} \tag{81}$$

Here, we used the fact that $\mathcal{E}_\chi^*$ on $\bar{A}$ does not change the reduced state on $\bar{C}'$, and that

$$\mathrm{Tr}_{\bar{A}\backslash A_l, \bar{C}'\backslash C_l'}\left[\mathcal{E}_\chi^*\left(\psi^{\otimes n}\right)\right] = \mathcal{E}_l(\psi^{A_lC_l'}),$$

because of $\Psi_{l'}^A = \psi_{l'}^A$. Combining (80) and (81), we obtain

$$nI(A:C')_\psi \leq I(\bar{A}:\bar{C}')_{\mathcal{E}_\chi^*(\psi^{\otimes n})} + 4n\eta(\zeta_\Psi(2\epsilon))\log d_A. \tag{82}$$

Define

$$\psi_{n,\chi}^{\bar{A}\bar{C}'} := \frac{\Pi_\chi^A(\psi^{AC'})^{\otimes n}\Pi_\chi^A}{\mathrm{Tr}[\Pi_\chi(\psi^A)^{\otimes n}]}$$

and

$$\psi_n^{\hat{a}_0\hat{a}_R\bar{C}'} := (\mathcal{E}_2 \circ \mathcal{E}_1 \circ \mathcal{E}_{\Gamma_\chi})(\psi_{n,\chi}^{\bar{A}\bar{C}'})$$

as depicted in Figure 5. From Condition (22) and $\psi^A = \Psi^A$, we have $\|(\psi^{\otimes n})^{\bar{A}} - \chi^{\bar{A}}\|_1 \leq \epsilon$. Thus, due to (79) and Inequality (41), we have

$$\begin{aligned}&\left\|\mathcal{E}_\chi(\psi_{n,\chi}^{\bar{A}\bar{C}'}) - \mathcal{E}_\chi^*(\psi^{\otimes n})^{\bar{A}\bar{C}'}\right\|_1 \\ &\leq \left\|\psi_{n,\chi}^{\bar{A}\bar{C}'} - (\psi^{AC'})^{\otimes n}\right\|_1 \leq 2\sqrt{\epsilon},\end{aligned}$$

which leads to

$$I(\bar{A}:\bar{C}')_{\mathcal{E}_\chi^*(\psi^{\otimes n})} \leq I(\bar{A}:\bar{C}')_{\mathcal{E}_\chi(\psi_{n,\chi})} + 4n\eta(2\sqrt{\epsilon})\log d_A \tag{83}$$

by Inequality (49) and $d_{C'} \leq d_A$. By the data processing inequality, we also have

$$I(\bar{A}:\bar{C}')_{\mathcal{E}_\chi(\psi_{n,\chi})} \leq I(\hat{a}_0\hat{a}_R:\bar{C}')_{\psi_n}. \tag{84}$$

Consequently, we obtain from (82), (83) and (84) that

$$\begin{aligned}nI(A:C')_\psi \quad &\leq \quad I(\hat{a}_0\hat{a}_R:\bar{C}')_{\psi_n} \\ &\quad\quad +4n\left(\eta(2\sqrt{\epsilon}) + \eta(\zeta_\Psi(2\epsilon))\right)\log d_A.\end{aligned} \tag{85}$$

The QMIs in (85) are calculated as follows. First, from (25), we have

$$(\mathcal{E}_2 \circ \mathcal{E}_1 \circ \mathcal{E}_{\Gamma_\chi})(\chi^{\bar{A}}) = \chi_{sKI}^{\hat{a}_0\hat{a}_R} = \sum_i q_i|i\rangle\langle i|^{\hat{a}_0} \otimes \phi_i^{\hat{a}_R}. \tag{86}$$

Therefore, from the monotonicity of the trace distance under $\mathcal{E}_2 \circ \mathcal{E}_1 \circ \mathcal{E}_{\Gamma_\chi}$, Equality (22) and $\psi^A = \Psi^A$, we obtain

$$\left\|\psi_n^{\hat{a}_0\hat{a}_R} - \chi_{sKI}^{\hat{a}_0\hat{a}_R}\right\|_1 \leq \left\|(\psi^{\otimes n})^{\bar{A}} - \chi^{\bar{A}}\right\|_1 \leq \epsilon. \tag{87}$$

Due to (47), (48) and

$$\mathrm{dim}\mathcal{H}^{\hat{a}_0}, \mathrm{dim}\mathcal{H}^{\hat{a}_R} \leq \mathrm{dim}\mathcal{H}^{\bar{A}} = d_A^n,$$

(87) implies that

$$\begin{aligned}&|S(\hat{a}_0)_{\chi_{sKI}} - S(\hat{a}_0)_{\psi_n}| \leq n\eta(\epsilon)\log d_A, \\ &|S(\hat{a}_R|\hat{a}_0)_{\chi_{sKI}} - S(\hat{a}_R|\hat{a}_0)_{\psi_n}| \leq 3n\eta(\epsilon)\log d_A,\end{aligned}$$

and consequently, that

$$\begin{aligned}&S(\hat{a}_0)_{\psi_n} + 2S(\hat{a}_R|\hat{a}_0)_{\psi_n} \\ &\leq S(\hat{a}_0)_{\chi_{sKI}} + 2S(\hat{a}_R|\hat{a}_0)_{\chi_{sKI}} + 7n\eta(\epsilon)\log d_A.\end{aligned}$$

Since $\psi_n^{\hat{a}_0\hat{a}_R\bar{C}'}$ is a classical-quantum state between $\hat{a}_0$ and $\hat{a}_R\bar{C}'$, we obtain

$$\begin{aligned}&I(\hat{a}_0\hat{a}_R:\bar{C}')_{\psi_n} \\ = \quad &I(\hat{a}_0:\bar{C}')_{\psi_n} + I(\hat{a}_R:\bar{C}'|\hat{a}_0)_{\psi_n} \\ \leq \quad &S(\hat{a}_0)_{\psi_n} + 2S(\hat{a}_R|\hat{a}_0)_{\psi_n} \\ \leq \quad &S(\hat{a}_0)_{\chi_{sKI}} + 2S(\hat{a}_R|\hat{a}_0)_{\chi_{sKI}} + 7n\eta(\epsilon)\log d_A \\ = \quad &H(\{q_i\}_i) + 2\sum_i q_iS(\phi_i^{\hat{a}_R}) + 7n\eta(\epsilon)\log d_A,\end{aligned} \tag{88}$$

where the last equality follows from (86).

It is straightforward to obtain from (77) that

$$\begin{aligned}I(A:C')_\psi \quad &= \quad I(a_0a_La_R:c_0'c_R')_{\psi_{KI}} \\ &= \quad H(\{p_j\}_j) + 2\sum_j p_jS(\varphi_j^{a_R}).\end{aligned} \tag{89}$$

Combining (85), (88) (89), we obtain

$$\begin{aligned} & n\left(H(\{p_j\}_j)+2\sum_j p_j S(\varphi_j^{a_R})\right) \\ & \leq H(\{q_i\}_i)+2\sum_i q_i S(\phi_i^{\hat{a}_R})+n\zeta'_{\Psi}(\epsilon)\log d_A, \end{aligned}$$

where

$$\zeta'_{\Psi}(\epsilon)=11\eta(2\sqrt{\epsilon})+4\eta(\zeta_{\Psi}(2\epsilon)) \tag{90}$$

and ζ_{Ψ} is a function defined by (78). Thus we finally arrive at (23). ■

E. Convergence of ζ_{Ψ}

We prove that $\zeta_{\Psi}(\epsilon)$ defined by (78) satisfies $\lim_{\epsilon\to 0}\zeta_{\Psi}(\epsilon)=0$, based on an idea used in [25]. Due to the Choi-Jamiolkowski isomorphism, $\mathfrak{E}$ can be identified with $\mathcal{S}(\mathcal{H}^A\otimes\mathcal{H}^A)$. Hence $\mathfrak{E}$ is compact, which implies that the supremum in (78) can actually be the maximum:

$$\zeta_{\Psi}(\epsilon)=\max_{\mathcal{E}\in\mathfrak{E}}\{g(\mathcal{E})|f(\mathcal{E})\leq\epsilon\}.$$

Hence we have that

$$\forall\epsilon>0,\ \exists\mathcal{E}\in\mathfrak{E}\ :\ g(\mathcal{E})=\zeta_{\Psi}(\epsilon),\ f(\mathcal{E})\leq\epsilon.$$

Define $\alpha:=\lim_{\epsilon\to 0}\zeta_{\Psi}(\epsilon)$. Due to the monotonicity, we have $\zeta_{\Psi}(\epsilon)\geq\alpha$ for all $\epsilon>0$. Consequently, we have that

$$\forall\epsilon>0,\ \exists\mathcal{E}\in\mathfrak{E}\ :\ g(\mathcal{E})\geq\alpha,\ f(\mathcal{E})\leq\epsilon. \tag{91}$$

Define $\mathfrak{E}_\alpha:=\{\mathcal{E}\in\mathfrak{E}\mid g(\mathcal{E})\geq\alpha\}$. Due to the continuity of g, $\mathfrak{E}_\alpha$ is a closed subset of $\mathfrak{E}$. Hence

$$\beta:=\min_{\mathcal{E}\in\mathfrak{E}_\alpha}f(\mathcal{E})$$

exists due to the continuity of f. By definition, we have that

$$\forall\mathcal{E}\in\mathfrak{E}:\ g(\mathcal{E})\geq\alpha\Rightarrow f(\mathcal{E})\geq\beta. \tag{92}$$

Suppose now that $\alpha>0$. We have $f(\mathcal{E})>0$ for all $\mathcal{E}\in\mathfrak{E}_\alpha$ due to Lemma 5. Thus we have $\beta>0$, in which case (92) contradicts with (91) because ϵ can be arbitrarily small. ■

APPENDIX C
PROOF OF THEOREM 10

In this Appendix, we prove Theorem 10 based on irreducibility of the KI decomposition.

A. Irreducibility of the KI decomposition

Similarly to the irreducibility of the KI decomposition of a set of states presented in Lemma 2, the KI decomposition of a bipartite state defined by Definition 3 also has a property of irreducibility as follows.

Lemma 15 Suppose the KI decomposition of Ψ^{AC} on A is given by

$$\Psi_{KI}^{AC}=\sum_{j\in J}p_j|j\rangle\langle j|^{a_0}\otimes\omega_j^{a_L}\otimes\varphi_j^{a_RC},$$

and define $\varphi_{j,kl}:=\langle k|^C\varphi_j^{a_RC}|l\rangle^C$, where $\{|k\rangle\}_k$ is an orthonormal basis of $\mathcal{H}^C$. Then the following two properties hold.

1) If a linear operator N on $\mathcal{H}_j^{a_R}:=\mathrm{supp}[\varphi_j^{a_R}]$ satisfies $p_jN\varphi_{j,kl}=p_j\varphi_{j,kl}N$ for all k and l, then $N=cI_j^{a_R}$ for a complex number c, where $I_j^{a_R}$ is the identity operator on $\mathcal{H}_j^{a_R}$.
2) If a linear operator $N:\mathcal{H}_j^{a_R}\to\mathcal{H}_{j'}^{a_R}$ $(j\neq j')$ satisfies $p_jN\varphi_{j,kl}=p_{j'}\varphi_{j',kl}N$ for all k and l, then $N=0$.

Proof: Define

$$\begin{aligned} p_M &:= \mathrm{Tr}[M^C\Psi^{AC}M^{\dagger C}], \\ \Psi_M &:= p_M^{-1}\mathrm{Tr}_C[M^C\Psi^{AC}M^{\dagger C}], \\ \varphi_{j,M}^{a_R} &:= p_M^{-1}\mathrm{Tr}_C[M^C\varphi_j^{a_RC}M^{\dagger C}] \end{aligned}$$

for $M\in\mathcal{L}(\mathcal{H}^C)$. The set of steerable states corresponding to (4) is given by $\mathfrak{S}_{\varphi^{C\to A}}:=\{\Psi_M\}_{M\in\mathcal{L}(\mathcal{H}^C)}$. Hence the KI isometry Γ on A with respect to Ψ^{AC} is equal to that with respect to $\mathfrak{S}_{\varphi^{C\to A}}$ by Definition 3. Thus Ψ_M is decomposed as

$$\Gamma\Psi_M\Gamma^\dagger=\sum_{j\in J}p_j|j\rangle\langle j|^{a_0}\otimes\omega_j^{a_L}\otimes\varphi_{j,M}^{a_R},$$

where $\{\varphi_{j,M}^{a_R}\}_{M\in\mathcal{L}(\mathcal{H}^C)}$ is a set of states which is irreducible in the sense of Lemma 2.

To prove Property 1), suppose that $N\in\mathcal{L}(\mathcal{H}_j^{a_R})$ satisfies $p_jN\varphi_{j,kl}=p_j\varphi_{j,kl}N$ for all k and l. Since $\varphi_{j,M}$ is decomposed as $\varphi_{j,M}=\sum_{k,l}\langle l|M^\dagger M|k\rangle\varphi_{j,kl}$, it follows that $p_jN\varphi_{j,M}=p_j\varphi_{j,M}N$ for all $M\in\mathcal{L}(\mathcal{H}^C)$. Hence we obtain Property 1) due to the irreducibility of $\{\varphi_{j,M}^{a_R}\}_{M\in\mathcal{L}(\mathcal{H}^C)}$. Property 2) is proved in a similar vein. ■

B. Proof of Theorem 10

Let us first adduce a useful lemma regarding fixed points of the adjoint map of a linear CPTP map.

Lemma 16 (See Lemma 11 in [1].) Let $\mathcal{E}$ be a linear CPTP map on $\mathcal{S}(\mathcal{H})$, the Kraus representation of which is given by $\mathcal{E}(\cdot)=\sum_k E_k(\cdot)E_k^\dagger$. Let $\mathcal{E}^*$ be the adjoint map of $\mathcal{E}$ defined by $\mathcal{E}^*(\cdot)=\sum_k E_k^\dagger(\cdot)E_k$. Then $X\in\mathcal{L}(\mathcal{H})$ satisfies $\mathcal{E}^*(X)=X$ if and only if $[E_k,X]=[E_k^\dagger,X]=0$ for all k.

The proof of Theorem 10 proceeds as follows. Let Γ be the KI isometry on A with respect to Ψ^{AC}, and let

$$\hat{\Psi}^{AC}:=\Gamma^A\Psi^{AC}\Gamma^{\dagger A}=\sum_{j\in J}p_j|j\rangle\langle j|^{a_0}\otimes\omega_j^{a_L}\otimes\varphi_j^{a_RC}$$

be the KI decomposition of Ψ^{AC} on A. We have

$$\begin{aligned} (\hat{\Psi}^{AC})^{\frac{1}{2}} &= \sum_{j\in J}\sqrt{p_j}|j\rangle\langle j|^{a_0}\otimes(\omega_j^{a_L})^{\frac{1}{2}}\otimes(\varphi_j^{a_RC})^{\frac{1}{2}}, \\ (\hat{\Psi}^{A})^{-\frac{1}{2}} &= \sum_{j\in J}\frac{1}{\sqrt{p_j}}|j\rangle\langle j|^{a_0}\otimes(\omega_j^{a_L})^{-\frac{1}{2}}\otimes(\varphi_j^{a_R})^{-\frac{1}{2}} \end{aligned}$$

and

$$(\hat{\Psi}^{AC})^{\frac{1}{2}}(\hat{\Psi}^{A})^{-\frac{1}{2}}=\sum_{j\in J}|j\rangle\langle j|^{a_0}\otimes I_j^{a_L}\otimes(\varphi_j^{a_RC})^{\frac{1}{2}}(\varphi_j^{a_R})^{-\frac{1}{2}}.$$

Hence the Kraus operators of $\mathcal{E}$ defined by (28) is decomposed as (29).

It follows from (11) that $\mathcal{E}(\Psi^A) = \Psi^A$. Due to Lemma 16, we have

$$\forall k,l\,; \quad [E_{kl}, \Psi^A] = 0,$$

or equivalently, have

$$\forall k,l\,; \quad [\hat{E}_{kl}, \hat{\Psi}^A] = 0,$$

from which it follows that

$$\forall j,k,l\,; \quad [e_{j,kl}, \varphi_j^{a_R}] = 0.$$

Using (30), we obtain

$$\forall j,k,l\,; \quad [\varphi_{j,kl}, \varphi_j^{a_R}] = 0,$$

where $\varphi_{j,kl} := \langle k|^C \varphi_j^{a_R C} |l\rangle^C$. Therefore, due to the irreducibility of the KI decomposition, we have that

$$\varphi_j^{a_R} = \pi_j^{a_R} := I_j^{a_R} / (\mathrm{dim}\mathcal{H}_j^{a_R}),$$

and consequently, that

$$e_{j,kl} = (\mathrm{dim}\mathcal{H}_j^{a_R})^{\frac{1}{2}} \varphi_{j,kl},$$

which implies the irreducibility of $\{e_{j,kl}\}_{k,l}$.

From (28), for any $\hat{\tau} = \Gamma\tau\Gamma^\dagger$ ($\tau \in \mathcal{S}(\mathcal{H}^A)$), we have

$$\langle j|^{a_0} \hat{\mathcal{E}}(\hat{\tau}) |j'\rangle^{a_0} = (\mathrm{id}^{a_L} \otimes \mathcal{E}_{jj'}^{a_R})(\langle j|^{a_0} \hat{\tau} |j'\rangle^{a_0}),$$

where $\mathcal{E}_{jj'}$ is a linear map on $\mathcal{L}(\mathcal{H}^{a_R})$ defined by

$$\mathcal{E}_{jj'}(\cdot) = \sum_{kl} e_{j,kl} (\cdot) e_{j',kl}^\dagger.$$

Thus we have

$$\langle j|^{a_0} \hat{\mathcal{E}}_\infty(\hat{\tau}) |j'\rangle^{a_0} = (\mathrm{id}^{a_L} \otimes \mathcal{E}_{\infty,jj'}^{a_R})(\langle j|^{a_0} \hat{\tau} |j'\rangle^{a_0}),$$

where $\mathcal{E}_{\infty,jj'}$ is a linear map on $\mathcal{L}(\mathcal{H}^{a_R})$ defined by

$$\mathcal{E}_{\infty,jj'} := \lim_{n\to\infty} \frac{1}{N} \sum_{n=1}^{N} \mathcal{E}_{jj'}^n.$$

Therefore, from

$$|\Psi_{KI}\rangle = \sum_{j\in J} \sqrt{p_j} |j\rangle^{a_0} |j\rangle^{b_0} |\omega_j\rangle^{a_L b_L} |\varphi_j\rangle^{a_R b_R C},$$

we obtain

$$\begin{aligned} &\hat{\mathcal{E}}_\infty(|\Psi_{KI}\rangle\langle\Psi_{KI}|) \\ &= \sum_{jj'} |j\rangle\langle j|^{a_0} \hat{\mathcal{E}}_\infty(|\Psi_{KI}\rangle\langle\Psi_{KI}|) |j'\rangle\langle j'|^{a_0} \\ &= \sum_{jj'} \sqrt{p_j p_{j'}} |j\rangle\langle j'|^{a_0} \otimes |j,\omega_j\rangle\langle j',\omega_{j'}|^{b_0 a_L b_L} \\ &\qquad\qquad \otimes \mathcal{E}_{\infty,jj'}^{a_R}(|\varphi_j\rangle\langle\varphi_{j'}|^{a_R b_R C}). \end{aligned} \tag{93}$$

Consider that we have $\mathcal{E} \circ \mathcal{E}_\infty = \mathcal{E}_\infty$, and thus have $\mathcal{E}_\infty^A(\Psi_\infty^{ABC}) = \Psi_\infty^{ABC}$. It follows that

$$\forall k,l\,; \quad [E_{kl}^A \otimes I^{BC}, \Psi_\infty^{ABC}] = 0,$$

and consequently, that

$$\forall k,l\,; \quad [\hat{E}_{kl}^A \otimes I^{BC}, \hat{\mathcal{E}}_\infty(|\Psi_{KI}\rangle\langle\Psi_{KI}|)] = 0.$$

Due to (29) and (93), this is equivalent to

$$e_{j,kl} \mathcal{E}_{\infty,jj'}^{a_R}(|\varphi_j\rangle\langle\varphi_{j'}|^{a_R b_R C}) = \mathcal{E}_{\infty,jj'}^{a_R}(|\varphi_j\rangle\langle\varphi_{j'}|^{a_R b_R C}) e_{j',kl}^\dagger \quad (\forall j,j',k,l).$$

Hence we have

$$\mathcal{E}_{\infty,jj'}^{a_R}(|\varphi_j\rangle\langle\varphi_{j'}|^{a_R b_R C}) = \begin{cases} \pi_j^{a_R} \otimes \varphi_j^{b_R C} & (j = j') \\ 0 & (j \neq j') \end{cases}$$

due to the irreducibility of $\{e_{j,kl}\}_{k,l}$. From (93), we obtain

$$\begin{aligned} &\hat{\mathcal{E}}_\infty(|\Psi_{KI}\rangle\langle\Psi_{KI}|) \\ &= \sum_{j\in J} p_j |j,j,\omega_j\rangle\langle j,j,\omega_j|^{a_0 b_0 a_L b_L} \otimes \pi_j^{a_R} \otimes \varphi_j^{b_R C}. \end{aligned}$$

Since $\hat{\mathcal{E}}_\infty(|\Psi_{KI}\rangle\langle\Psi_{KI}|)$ and Ψ_∞^{ABC} are equivalent up to local isometries on A and B, we finally obtain

$$\begin{aligned} S(\Psi_\infty^{ABC}) &= H(\{p_j\}) + \sum_j p_j \left(S(\pi_j^{a_R}) + S(\varphi_j^{b_R C}) \right) \\ &= H(\{p_j\}) + 2\sum_j p_j S(\varphi_j^{a_R}) \\ &= \ \ M_{A|B}(\Psi^{ABC}), \end{aligned}$$

where we used the fact that $\varphi_j^{a_R} = \pi_j^{a_R}$ and that $\varphi_j^{a_R b_R C}$ is a pure state. ■

Remark: From (13) and (14), it is straightforward to verify that the statement of Theorem 10 does not depend on a particular choice of a purification of Ψ^A. That is, for any purification $|\Omega\rangle^{AA'}$ of Ψ^A, we have $M_{A|B}(\Psi^{ABC}) = S(\Omega_\infty^{AA'})$, where $\Omega_\infty^{AA'} := \mathcal{E}_\infty^A(|\Omega\rangle\langle\Omega|^{AA'})$. A purification of Ψ^A is simply obtained by

$$|\Omega\rangle^{AA'} = (\Psi^A)^{\frac{1}{2}} \sum_{k=1}^{d_A} |k\rangle^A |k\rangle^{A'},$$

and its matrix representation is given by

$$|\Omega\rangle\langle\Omega|^{AA'} = \sum_{klmn} [\Lambda_1]_{kl,mn} |k\rangle\langle l|^A \otimes |m\rangle\langle n|^{A'}.$$

The matrix elements of the generalized inverse matrix Λ_1^{-1} are given by

$$[\Lambda_1^{-1}]_{kl,mn} = \langle k|(\Psi^A)^{-\frac{1}{2}}|m\rangle\langle n|(\Psi^A)^{-\frac{1}{2}}|l\rangle.$$

In addition, the dimension of the eigensubspace of Λ_∞ corresponding to the eigenvalue 1 is at least 1, since we have $\mathcal{E}_\infty(I) = I$ due to the self-adjointness of $\mathcal{E}$. These facts justify the algorithm described in Section III.

APPENDIX D
PROOF OF INEQUALITY (33)

The first inequality in (33) is proved as follows. For an arbitrary n and $\epsilon > 0$, let $\mathcal{V}_n : \tau \mapsto 2^{-nR} \sum_{k=1}^{2^{nR}} V_k \tau V_k^\dagger$ be a random unitary operation on A^n, and let $\Upsilon^{A^n B^n C^n}$ be a Markov state conditioned by B^n such that

$$\left\| \mathcal{V}_n(\rho^{\otimes n}) - \Upsilon^{A^n B^n C^n} \right\|_1 \leq \epsilon. \tag{94}$$

Let $|\psi\rangle^{ABCD}$ be a purification of ρ^{ABC}, and E be a quantum system with dimension 2^{nR}. Defining an isometry $W : A^n \to EA^n$ by $W = \sum_{k=1}^{2^{nR}} |k\rangle^E \otimes V_k^{A^n}$, a Stinespring dilation of $\mathcal{V}_n$ is given by $\mathcal{V}_n(\tau) = \mathrm{Tr}_E[W\tau W^\dagger]$. Then a purification of $\rho_n'^{ABC} := \mathcal{V}_n(\rho^{\otimes n})$ is given by $|\psi_n'\rangle^{EA^nB^nC^nR^n} := W(|\psi\rangle^{ABCR})^{\otimes n}$. For this state, we have

$$\begin{aligned} nR \geq S(E)_{\psi_n'} &= S(A^nB^nC^nR^n)_{\psi_n'} \\ &\geq S(A^nB^nC^n)_{\psi_n'} - S(R^n)_{\psi_n'} \\ &= S(A^nB^nC^n)_{\rho_n'} - S(R^n)_{\psi^{\otimes n}} \\ &= S(A^nB^nC^n)_{\rho_n'} - nS(ABC)_\rho, \end{aligned} \tag{95}$$

where the second line follows from (44). From (94), we also have

$$\begin{aligned} & S(A^nB^nC^n)_{\rho_n'} \\ \geq\ & S(A^nB^nC^n)_\Upsilon - n\eta(\epsilon)\log\left(d_Ad_Bd_C\right) \\ =\ & S(A^nB^n)_\Upsilon + S(B^nC^n)_\Upsilon - S(B^n)_\Upsilon \\ & \quad -n\eta(\epsilon)\log\left(d_Ad_Bd_C\right) \\ \geq\ & S(A^nB^n)_{\rho_n'} + S(B^nC^n)_{\rho_n'} - S(B^n)_{\rho_n'} \\ & \quad -4n\eta(\epsilon)\log\left(d_Ad_Bd_C\right) \\ \geq\ & S(A^nB^n)_{\rho^{\otimes n}} + S(B^nC^n)_{\rho^{\otimes n}} - S(B^n)_{\rho^{\otimes n}} \\ & \quad -4n\eta(\epsilon)\log\left(d_Ad_Bd_C\right) \\ =\ & n\left(S(AB)_\rho + S(BC)_\rho - S(B)_\rho\right) \\ & \quad -4n\eta(\epsilon)\log\left(d_Ad_Bd_C\right). \end{aligned} \tag{96}$$

Here, the second line follows by Inequality (47); the third line because of Υ being a Markov state conditioned by B^n; the fourth line by Inequality (47); and the fifth line by the von Neumann entropy being nondecreasing under random unitary operations, in addition to $\rho_n'^{B^nC^n} = (\rho^{BC})^{\otimes n}$. From (95) and (96), we obtain

$$R \geq I(A:C|B)_\rho - 4\eta(\epsilon)\log\left(d_Ad_Bd_C\right),$$

which concludes the proof. ■
